Bacteria sense their own population size, tune the expression of responding genes, and behave accordingly to environmental stimuli by secreting signaling molecules. This phenomenon is termed as quorum sensing (QS). By exogenously manipulating the signal transduction bacterial population behaviors could be controlled, which may be done through quorum quenching (QQ). QS related regulatory networks have been proven their involvement in regulating many virulence determinants in pathogenic bacteria in the course of infections. Interfering with QS signaling system could be a novel strategy against bacterial infections and therefore requires more understanding of their fundamental mechanisms. Here we review the development of studies specifically on the inhibition of production of N-acyl-homoserine lactone (AHL), a common proteobacterial QS signal. The opportunistic pathogen, Pseudomonas aeruginosa, equips the alkylquinolone (AQ)-mediated QS which also plays crucial roles in its pathogenicity. The studies in QQ targeting on AQ are also discussed.

Keywords: quorum sensing, quorum quenching, N-acyl-homoserine lactone, Pseudomonas quinolone signal, Pseudomonas aeruginosa, alkylquinolone

INTRODUCTION

Quorum sensing (QS) is an intercellular communication mechanism of bacteria used to coordinate the activities of individual cells in population level in response to surroundings through production and perception of diffusible signal molecules. The signal synthase, signal receptor, and signal molecules are three essential elements of the basic QS circuit machinery. Genes encoded signal generating proteins are also included among the QS target genes. This forms an autoinduction feedback loop to modulate generation of signal molecules (Fuqua et al., 1994; Ng and Bassler, 2009; Williams and Cámara, 2009). Several bacterial behaviors including virulence factors expression, secondary metabolites production, biofilm formation, motility, and luminescence are regulated by QS (Antunes et al., 2010; LaSarre and Federle, 2013). QS system is part of global regulation networks in bacterial cell related to cyclic-di-GMP second messenger signaling pathways (Srivastava and Waters, 2012), small RNA regulation (Vakulskas et al., 2015), two-components systems (Okkotsu et al., 2014), toxin–antitoxin (Kumar and Engelberg-Kulka, 2014), flagella regulation (Atkinson et al., 2008), and protein secretion systems (Zheng et al., 2010;
AHL SYNTHESIS AND INHIBITION

More than 30 different AHLs have been identified. AHLs generally consist of a homoserine lactone ring and of a fatty acyl side chain ranging from 4 to 18 carbons (Chhabra et al., 2005). The regulation of bioluminescence in _Aliivibrio fischeri_ (former _Vibrio fischeri_) (Urbanczyk et al., 2007) is the archetypal example of AHL-QS. The genes for bioluminescence are encoded in an operon (_luxICDABE_) where _luxI_ encodes the AHL synthase that generates \(N-(3\text{-oxo-hexanoyl})\)-L-homoserine lactone (3-oxo-C6 HSL) and _luxCDAE_ encode for proteins responsible for bioluminescence production. This operon is regulated by the LuxR protein, a transcriptional regulator. Binding of 3-oxo-C6-HSL by LuxR activates the expression of the _luxICDABE_ operon which in turns results in the production of more of this signal molecule, through an autoinduction loop, and bioluminescence (Fuqua and Greenberg, 2002). S-adenosylmethionine (SAM) is the main amino acid substrate for the homoserine lactone ring, while the acyl chain of AHL is derived from a 6-carbon acyl-ACP (acyl carrier protein). The LuxI catalyzes the formation of an amide bond between the two substrates. SAM binds to the active site of LuxI, and then the acyl group from a specific acyl-ACP is transferred to the methionine on SAM and forms an amide bond. Lactonization of the intermediate results in the production of AHL and methylthioadenosine (MAT; Parsek et al., 1999). Two regions of LuxI are essential for the full function of the enzyme. Residues 25 to 104 are thought to be the region of the enzymatic catalysis, while residue 133 to 164 are involved in the selection of the appropriate acyl-ACP substrates (Hanzelka and Greenberg, 1996).

Homologs of _luxI_/ _luxR_ are involved in Gram-negative bacteria (Miller and Bassler, 2001; LaSarre and Federle, 2013). AHL synthases from more than 40 different bacteria share four conserved regions in their protein sequences and within them eight residues are completely conserved (Fuqua et al., 1994). The X-ray crystallography study of an AHL synthase Esal, a LuxI-type protein producing 3-oxo-C6-HSL from _Pantoea stewartii_ has been revealed (Watson et al., 2002). A model for catalyzing the amide bond between the two substrates based on this structural study has been proposed. Many of the conserved residues across LuxI-type synthases lie on the same face of the Esal and are localized in the active site in N-terminus. This supports a notion that SAM and acyl-ACP interact with this region. The presence or absence of a serine/threonine at residue 140 in AHL synthase may be crucial for selecting different acyl-ACP substrates. LasI, Esal, and LuxI which mainly produce 3-oxo-AHLs have a conserved threonine at this position whilst the absence of threonine at position 140 in RhII, CerI, SwrI, and Asal seems to preferentially produce AHLs lacking 3-oxo or 3-hydroxy moiety (Watson et al., 2002). The crystal structure of LasI, the synthase from _P. aeruginosa_ mainly produces \(N-(3\text{-oxododecanoyl})\)-homoserine lactone (3-oxo-C12-HSL), further reveals the mechanism of AHL synthesis. The conserved residues in LasI N-terminus form a binding pocket for SAM and the structure of the acyl-ACP binding pocket is formed as a tunnel which allow the binding of different acyl-ACPs with longer side chain in contrast to the restrictive hydrophobic pocket in...
Esai (Gould et al., 2004). The acceptance of various acyl-ACPs in LasI may explain the wild spectrum of AHL production profile in P. aeruginosa (Ortori et al., 2011).

N-acyl-homoserine lactone molecules act not only in bacterial communication but also in cross-kingdom conversation with eukaryotic cells (Joint et al., 2002; Twigg et al., 2013). AHLs modulate the behaviors of innate immune cells and interfere with the signaling pathways in epithelial cells (Holm and Vikström, 2014). Inhibition of AHLs production is the strategy to reduce the AHLs-mediated virulence factors and to prevent AHLs-promoted tissue damages and inflammation. To study the kinetic process of AHLs synthesis by RhlII from P. aeruginosa, the end products MTA and several substrate analogs including holo-ACP, sinefungin, D/L-S-adenosylhomocysteine, L-S-adenoslycysteine, and butyryl-SAM have been tested for their inhibition effects on AHLs production in vitro (Parsek et al., 1999). However their effects on QS and QS-related phenotypes in vivo are unclear (Rasmussen, 2006). More inhibitors targeting on the AHL synthesis precursors or their synthesis have been identified. A small molecule, triclosan, reduces AHL synthesis by inhibiting the precursor production from enoyl-ACP reductase (Huang and Schweizer, 1999). The 5-MAT/S-adenosyl-homocysteine nucleosidase (MTAN), which plays crucial part in both AHL and AI-2 synthesis, was inhibited by immucillin A (ImMa) derivatives and DADMe-ImMa derivatives (Singh et al., 2005a,b, 2006). These inhibitors not only show the effective potency on AHL synthesis but also inhibit the central amino acid and fatty acid metabolism which by which may affect other cellular functions. This imposes selective pressure to bacterial cells and increases the risk of resistance. For example P. aeruginosa develops resistance to triclosan because of active efflux pumps (Schweizer, 2003). Thus, it is necessary to identify inhibitors specifically targeting on AHLs synthesis without interrupting metabolism.

In Burkholderia glumae, the pathogen of rice grain rot, virulence factor biosynthesis and transportation, protein secretion and motility are controlled by N-octanoyl-HSL (C8-HSL) produced by Tofl. Two acyl-HSL analogs have been identified to inhibit the C8-HSL mediated QS. One of the inhibitor, E9C-3oxoC6, competitively inhibits C8-HSL binding to its cognate regulator, TolR. The other inhibitor, J8-C8 (N-3-oxocyclohex-1-enyl octanamide), inhibits C8-HSL synthesis in a dose-dependent manner. Crystal structure analysis suggested that the Tofl, which is similar to its homologues, LasI and Esai, consists of two substrate-binding sites (Watson et al., 2002; Gould et al., 2004; Chung et al., 2011). A putative pocket in apo-Tofl structure has been identified which is bound by J8-C8. This study suggested J8-C8 occupies the acyl-ACP substrate-binding site of Tofl and inhibits its function (Chung et al., 2011).

Besides rationally designed analogs, natural products isolated from various sources also exhibit QQ properties (Koh et al., 2013). Three pure botanic compounds, salicylic acid, tannic acid, and trans-cinnamaldehyde, showed the inhibition on P. aeruginosa AHL synthase. Further liquid chromatography–mass spectrometry (LC–MS) analysis suggested the trans-cinnamaldehyde specifically targets short-chain AHL synthase RhlII. The RhlII/R-QS in P. aeruginosa is involved in the production of pyocyanin, a green phenazine pigment functioning as a toxin and promoting biofilm formation. The trans-cinnamaldehyde inhibits pyocyanin production in a dose-dependent manner. Successful molecule docking suggested trans-cinnamaldehyde occupies the SAM substrate binding sites of RhlII counterpart, LasI in P. aeruginosa and the acyl-chain substrate binding site of Esai in Pa. stewartii (Chang et al., 2014). Furthermore cinnamaldehyde and its derivatives target on AI-2 based LuxR in Vibrio sp. and reduce the LuxR DNA binding ability which lead to the reduction of biofilm formation, sensitivity to starvation and antibiotics treatment, reduction of pigment and virulence factors production and attenuated pathogenicity (Brackman et al., 2008, 2011). These studies suggested the potentiality of cinnamaldehyde as a QQ compound against bacteria infections.

### QUENCHING AQ-MEDIATED QS

A non-AHL signaling molecule produced by P. aeruginosa was described and termed as PQS (Pseudomonas quinolone signal) by Pesci et al. (1999). This molecule was chemically characterized as 2-heptyl-3-hydroxy-4-(1H)-quinolone, part of the 4-hydroxy-2-alkyl quinoline series (HAQ; Pesci et al., 1999). Other major molecules comprised the C7 and C9 long alkyl chain including 2-heptyl-4-quinolone (HHQ), 2-nonyl-4-quinolone (NHQ), 2-heptyl-4-quinolone N-oxide (HHQNO), 2-heptyl-4-hydroxyquinolone N-oxide (HQNO) and 2-nonyl-4-hydroxyquinolone N-oxide (NNQNO) are also produced by P. aeruginosa. More than 50 different AQs have been found in P. aeruginosa. These molecules all belong to the family of 2-alkyl-4-quinolones (AQs) which have been previously studied for their antimicrobial properties (Moffitt et al., 2011; Ortori et al., 2011).

2-heptyl-4-quinolone and Pseudomonas quinoline signal are the major AQ–QS signaling molecules in P. aeruginosa. The AQ–QS system consists of multiple genes. The pqsABCDE in an operon are essential for AQs synthesis. PqsA catalyzes the conversion from anthranilic acid produced by pheAB, which are adjacent to pqsABCDE operon, to anthraniloyl-coenzyme A (CoA). PqsD then condenses anthraniloyl moiety from anthraniloyl-CoA with malonyl-CoA to form intermediate 2-aminozoyl-acetyl-CoA (2-ABA-CoA) for subsequently synthesizing 2,4-dihydroxyquinolone (DHQ) with unknown function or 2-aminozoylacetate (2-ABA). The decarboxylating coupling of 2-ABA to an octanoate group linked to PqsBC produces HQQ (Bera et al., 2009; Dulcey et al., 2013). HHQ acts as a signaling molecule or can then be transformed to PQS by the mono-oxygenase, PqsH (Pesci et al., 1999; Diggle et al., 2006). PqsE is required for P. aeruginosa virulence in plant and animals infection models and biofilm formation (Rampioni et al., 2010). A recent study suggested PqsE is also involved in the HHQ synthesis as a thioesterase, hydrolyzing the 2-ABA-CoA to form 2-ABA. Although PqsE plays crucial role in P. aeruginosa pathogenicity, its catalytic role in AQ biosynthesis can be replaced by a broad specificity thioesterase, TesB (Drees and Fetzner, 2015). Two other genes, pqsH and pqsL, involved in AQ synthesis are located separately.

elsewhere on the chromosome in P. aeruginosa. PqsH, FAD-dependent monoxygenase, is required for the conversion of HHQ into PQS. PqsL is also a monoxygenase which is required for HQNO synthesis (Heeb et al., 2011). PQS or HHQ binds to and activates the LysR-type transcriptional regulator PqsR (also known as MvfR), which in turn induces the expression of the pqsABCDE operon and possibly the phnAB operon and triggers the typical QS autoinducing response enhancing AQ biosynthesis (Maddocks and Oyston, 2008; Heeb et al., 2011).

Alkylquinolone–quorum sensing cooperates with the AHL-QS systems, lasI/R and rhlI/R, in P. aeruginosa (Xiao et al., 2006; Heeb et al., 2011). PQS has been shown to regulate the expression of the AHL synthase gene rhlI (Pesci et al., 1999; McKnight et al., 2000). Furthermore, it has been demonstrated that PQS is essential for the activation of certain rhl-dependent genes (Diggle et al., 2003). The las QS system increases the expression of pqsR and pqsA as well as controlling the expression of pqsH indicating that las acts as a positive regulator of PQS (Déziel et al., 2004; Xiao et al., 2006). However, the biosynthesis of PQS only partially relies on the las system since PQS is still produced in the absence of lasR (Diggle et al., 2003). In contrast to the las QS system, the rhl system negatively regulates the PQS production (Xiao et al., 2006; Heeb et al., 2011).

Alkylquinolone–quorum sensing also plays important roles in pathogenicity. Mutants on AQ–QS showed reduced P. aeruginosa virulence in infection models (Cao et al., 2001; Diggle et al., 2003; Déziel et al., 2004). These results suggest that PQS or HHQ signaling pathway could be a novel target against P. aeruginosa infections. A sesquiterpene, farnesol produced by the fungus Candida albicans, decreases the level of pqsA expression by interfering with PqsR-mediated transcription activation and sequentially reduces the PQS and PQS-regulated pyocyanin production. However, in the PQS-defective lasR mutant farnesol restores PQS production by inducing PqsH via RhlI/C4-HSL activation (Cugini et al., 2007, 2010). Around 50% of strains isolated from lungs of late stage cystic fibrosis (CF) patients are deficient in lasR function (Winstanley and Fothergill, 2009). The fungal–bacterial communication via farnesol is still unclear and may provide a new target for mitigating bacterial chronic infection in CF lungs.

A monomeric enzyme, Hod (3-hydroxy-2-methyl-4(1H)-quinolone 2,4-dioxygenase) from Arthrobacter sp. strain Rue61a involved in the degradation of 2-methylquinoline (quinaldine), is able to cleave PQS to N-octanoylanthranilic acid and carbon monoxide but not HHQ. Exogenous Hod reduces the PQS production and PQS-regulated virulence factors, lectin A, pyocyanin, and rhamnolipids in P. aeruginosa. Hod also attenuates the pathogenicity of P. aeruginosa in a plant leaf infection model (Pustelnik et al., 2009). It has been reported that, a group of analogs of PQS precursor anthranilic acid (AA) including methylntranilate (MA), 2-amino-6-fluorobenzoic acid (6FABA), 2-amino-6-chlorobenzoic acid (6CABA), and 2-amino-4-chlorobenzoic acid (4CABA), acts as competitors for PqsA active site and as inhibitors for HHQ and PQS production resulting in reduced pathogenicity of P. aeruginosa in mice infection models (Calfee et al., 2001; Lesic et al., 2007). Recently Soh et al. (2015) reports an environmental bacterium, Achromobacter xylosidans Q19 from...
**CONCLUSION**

Here we summarize recent studies of AHL synthesis inhibition and QQ on *P. aeruginosa* AQ–QS (Table 1). Although QS is an ideal target to attenuate bacterial virulence and pathogenicity, several studies warn that bacteria rapidly evolve and spread the resistance against QS inhibitors like the fate of antibiotics (García-Contreras et al., 2013; Kalia et al., 2013). Furthermore Decho et al. (2010) suggested that the biologically or chemically modified signals might interact with unexpected signal receptors for unpredicted outcomes in the complex natural environments. Little is known about the effects of QS inhibitors or enzymes on the broader microorganisms’ communities or the fate of products from signal molecules degradation and modifications in the environments (Decho et al., 2010). Many questions remain for further investigation. Thus it is highly desired to further investigate the virulent roles of QS signals in infections and to explore the strategy to eliminate their production rather than to modify or to degrade them for diminishing unpredicted impacts to environments.
