Partial differential systems with nonlocal nonlinearities: Generation and solutions

Margaret Beck · Anastasia Doikou · Simon J.A. Malham · Ioannis Stylianidis

30th January 2018

Abstract We develop a method for generating solutions to large classes of evolutionary partial differential systems with nonlocal nonlinearities. For arbitrary initial data, the solutions are generated from the corresponding linearized equations. The key is a Fredholm integral equation relating the linearized flow to an auxiliary linear flow. It is analogous to the Marchenko integral equation in integrable systems. We show explicitly how this can be achieved through several examples including reaction-diffusion systems with nonlocal quadratic nonlinearities and the nonlinear Schrödinger equation with a nonlocal cubic nonlinearity. In each case we demonstrate our approach with numerical simulations. We discuss the effectiveness of our approach and how it might be extended.

1 Introduction

Our concern is the generation of solutions to nonlinear partial differential equations. In particular, as is natural, to develop methods that generate such solutions from solutions to the corresponding linearized equations. Herein we do not restrict ourselves to soliton equations, nor indeed to integrable systems. We do not demand nor require the existence of a Lax pair. However our approach herein as it stands at this time, only applies to classes of partial differential systems with nonlocal nonlinearities. Naturally we seek to extend it to more general systems and we discuss how this might be achieved in our conclusions. However let us return to what we have achieved thus far.
and intend to achieve herein. In Beck, Doikou, Malham and Stylianidis [5] we demonstrated the approach we developed indeed works for large classes of scalar partial differential equations with quadratic nonlocal nonlinearities. For example we demonstrated, for general smooth initial data \(g_0 = g_0(x, y)\) with \(x, y \in \mathbb{R}\) and some time \(T > 0\) of existence, how to construct solutions \(g \in C^\infty([0, T]; C^\infty(\mathbb{R}^2; \mathbb{R}) \cap L^2(\mathbb{R}^2; \mathbb{R}))\) to partial differential equations of the form

\[
\partial_t g(x, y; t) = d(\partial_x g)(x, y; t) - \int_{\mathbb{R}} g(x, z; t) b(\partial_x g)(z, y; t) \, dz.
\]

In this equation, \(d = d(\partial_x)\) is a polynomial function of the partial differential operator \(\partial_x\) with constant coefficients, while \(b\) is either a polynomial function \(b = b(\partial_x)\) of \(\partial_x\) with constant coefficients, or it is a smooth bounded function \(b = b(x)\) of \(x\). Thus the linear term \(d(\partial_x) g(x, y; t)\) is quite general, while the quadratic nonlinear term, whilst also quite general, has the nonlocal form shown. Hereafter for convenience we denote this nonlocal product by \(\langle \ast \rangle\), defined for any two functions \(g, g' \in L^2(\mathbb{R}^2; \mathbb{R})\) by

\[
(g \ast (bg'))(x, y) := \int_{\mathbb{R}} g(x, z) g'(z, y) \, dz.
\]

Hence for example the nonlocal nonlinear term above can be expressed as \((g \ast (bg))(x, y; t)\).

In this paper we extend our method in two directions. First we extend it to classes of systems of partial differential equations with quadratic nonlocal nonlinearities. For example we demonstrate, for general smooth initial data \(u_0 = u_0(x, y)\) and \(v_0 = v_0(x, y)\) with \(x, y \in \mathbb{R}\) and some time \(T > 0\), how to construct solutions \(u, v \in C^\infty([0, T]; C^\infty(\mathbb{R}^2; \mathbb{R}) \cap L^2(\mathbb{R}^2; \mathbb{R}))\) to partial differential systems with quadratic nonlocal nonlinearities of the form

\[
\partial_t u = d_{11}(\partial_x) u + d_{12}(\partial_x) v - u \ast (b_{11} u) - u \ast (b_{12} v) - v \ast (b_{11} u) - v \ast (b_{12} v),
\]

\[
\partial_t v = d_{11}(\partial_x) v + d_{12}(\partial_x) u - u \ast (b_{11} v) - u \ast (b_{12} u) - v \ast (b_{11} v) - v \ast (b_{12} u).
\]

In this formulation the operators \(d_{11} = d_{11}(\partial_x)\), \(d_{12} = d_{12}(\partial_x)\) are polynomials of \(\partial_x\) analogous to the operator \(d\) above, the operation \(\ast\) is as defined above and \(b_{11}\) and \(b_{12}\) are analogous functions to the function \(b\) defined above. In the special case that \(d_{11}\) and \(d_{12}\) are both constant multiples of \(\partial_x^2\) and \(b_{11}\) and \(b_{12}\) are scalar constants, then the system of equations for \(u\) and \(v\) above represent a system of reaction-diffusion equations with nonlocal nonlinear reaction/interaction terms.

Second, with a slight modification, we extend our approach to classes of partial differential equations with cubic and higher odd degree nonlocal nonlinearities. In particular, for general smooth \(\mathbb{C}\)-valued initial data \(g_0 = g_0(x, y)\) with \(x, y \in \mathbb{R}\) and some time \(T > 0\), we demonstrate how to construct solutions \(g \in C^\infty([0, T]; C^\infty(\mathbb{R}^2; \mathbb{C}) \cap L^2(\mathbb{R}^2; \mathbb{C}))\) to nonlocal nonlinear partial differential equations of the form \((i = \sqrt{-1})\),

\[
i \partial_t g = d(\partial_x) g + g \ast f^*(g \ast g').
\]
Here with a slight abuse of notation, we suppose

\[(g \ast g^\dagger)(x, y) := \int_\mathbb{R} g(x, z) g^*(y, z) \, dz,\]

where \(g^*\) denotes the complex conjugate of \(g\). Our method works for any choice of \(d\) of the form \(d = \text{ib}(\check{\alpha})\), where \(b\) is any constant coefficient polynomial with only even degree terms of its argument. Further, it works for any function \(f^*\) with a power series representation with infinite radius of convergence and real coefficients \(a_m\) of the form

\[f^*(c) = i \sum_{m \geq 0} a_m c^{m}.\]

The expression \(c^{m}\) represents the \(m\)-fold \(*\) product of \(c \in L^2(\mathbb{R}; \mathbb{C})\).

Our method is based on the development of Grassmannian flows from linear subspace flows as follows; see Beck et al. [5]. Formally, suppose that \(Q = Q(t)\) and \(P = P(t)\) are linear operators satisfying the following linear system of evolution equations in time \(t\),

\[\partial_t Q = A Q + B P \quad \text{and} \quad \partial_t P = C Q + D P.\]

We assume that \(A\) and \(C\) are bounded linear operators, while \(B\) and \(D\) may be bounded or unbounded operators. Throughout their time interval of existence say on \([0, T]\) with \(T > 0\), we suppose \(Q - \text{id}\) and \(P\) to be compact operators, indeed Hilbert–Schmidt operators. Thus \(Q\) itself is a Fredholm operator. If \(B\) and \(D\) are unbounded operators we suppose \(Q - \text{id}\) and \(P\) to lie in a suitable subset of the class of Hilbert–Schmidt operators characterised by their domains. We now posit a relation between \(P = P(t)\) and \(Q = Q(t)\) mediated through a compact Hilbert–Schmidt operator \(G = G(t)\) as follows,

\[P = G Q.\]

Suppose we now differentiate this relation with respect to time using the product rule and insert the evolution equations for \(Q = Q(t)\) and \(P = P(t)\) above. If we then equivalence by the Fredholm operator \(Q = Q(t)\), i.e. post-compose by \(Q^{-1} = Q^{-1}(t)\) on the time interval on which it exists, we obtain the following Riccati evolution equation for \(G = G(t)\),

\[\partial_t G = C + D G - G (A + B G).\]

This demonstrates how certain classes of quadratically nonlinear operator-valued evolution equations, i.e. the equation for \(G = G(t)\) above, can be generated from a coupled pair of linear operator-valued equations, i.e. the equations for \(Q = Q(t)\) and \(P = P(t)\) above. We think of the prescription just given as the “abstract” setting in which \(Q = Q(t), P = P(t)\) and \(G = G(t)\) are operators of the classes indicated. Note that often we will take \(A = C = 0\) and the equations for \(Q = Q(t)\) and \(P = P(t)\) above are \(\partial_t Q = B P\) and \(\partial_t P = D P\).

In this case, once we have solved the evolution equation for \(P = P(t)\), we can then solve the equation for \(Q = Q(t)\).
We can generate cubic and higher odd degree classes of nonlinear operator-valued evolution equations analogous to that for \( G = G(t) \) above by slightly modifying the procedure we outlined. Again, formally, suppose that \( Q = Q(t) \) and \( P = P(t) \) are linear operators satisfying the following linear system of evolution equations in time \( t \),

\[
\dot{c}_t Q = f(PP^\dagger)Q \quad \text{and} \quad \dot{c}_t P = DP,
\]

where \( P^\dagger = P^\dagger(t) \) denotes the operator adjoint to \( P = P(t) \) and \( f \) is a function with a power series expansion with infinite radius of convergence. The operator \( D \) may be a bounded or unbounded operator. In addition we require that \( Q = Q(t) \) satisfies the constraint \( QQ^\dagger = \text{id} \) while it exists. Indeed as above, throughout their time interval of existence say on \([0, T]\) with \( T > 0 \), we suppose \( Q - \text{id} \) and \( P \) to be Hilbert–Schmidt operators. If \( D \) is unbounded then we suppose \( P \) lies in a suitable subset of the class of Hilbert–Schmidt operators characterised by its domain. We can think of the equations above as corresponding to the previous set of equations for \( Q = Q(t) \) and \( P = P(t) \) in the paragraph above with the choice \( B = C = O \) and \( A = f(PP^\dagger) \). We emphasize however, once we have solved the evolution equation for \( P = P(t) \), the evolution equation for \( Q = Q(t) \) is linear. We posit the same linear relation \( P = GQ \) between \( P \) and \( Q \) as before, mediated through a compact Hilbert–Schmidt operator \( G = G(t) \). Then a direct analogous calculation to that above, differentiating this relation with respect to time and so forth, reveals that \( G = G(t) \) satisfies the evolution equation

\[
\dot{c}_t G = DG - G f(GG^\dagger).
\]

The requirement that \( Q = Q(t) \) must satisfy the constraint \( QQ^\dagger = \text{id} \) induces the requirement that \( f^\dagger = -f \). Hence again, we can generate certain classes of cubic and higher odd degree nonlinear operator-valued evolution equations, like that for \( G = G(t) \) just above, by first solving the operator-valued linear evolution equation for \( P = P(t) \) and then solving the operator-valued linear evolution equation for \( Q = Q(t) \). To summarize, we observe that in both procedures above, there were three essential components as follows, a linear:

1. Base equation: \( \dot{c}_t P = DP \);
2. Auxiliary equation: \( \dot{c}_t Q = BP \) or \( \dot{c}_t Q = f(PP^\dagger)Q \);
3. Riccati relation: \( P = GQ \).

We now make an important observation and ask two crucial questions. First, we observe that solving each of the three linear equations above in turn actually generates solutions \( G = G(t) \) to the classes of operator-valued nonlinear evolution equations shown above. Second, in the appropriate context, can we interpret the operator-valued nonlinear evolution equations above as nonlinear partial differential equations? Third, if so, what classes of nonlinear partial differential equations fit into this context and can be solved in this way? In other words, can we solve the inverse problem: given a nonlinear partial differential equation, can we fit it into the context above (or an analogous context)
In the last step we utilized the associativity property $Bp$ in the “abstract” operator-valued setting, we can differentiate the relation $\delta$ is the identity operator with respect to the $p$. We can express this more succinctly as

$$
\text{equation}
$$

The linear Riccati relation in this context takes the form of the linear Fredholm equation

$$
p(x,y;t)=g(x,y;t)+\int_{\mathbb{R}} g(x,z;t) q'(z,y;t) \, dz.
$$

We can express this more succinctly as $p = g + g \bullet q'$ or $p = g \bullet (\delta + q')$, where $\delta$ is the identity operator with respect to the $\bullet$ product. As described above in the “abstract” operator-valued setting, we can differentiate the relation $p = g \bullet (\delta + q')$ with respect to time using the product rule and insert the base and linear equations $\partial_t p = \partial_t^2 p$ and $\partial_t q' = p$ to obtain the following

$$(\partial_t g) \bullet (\delta + q') = \partial_t p - g \bullet \partial_t q'$$

$$= (\partial_t^2 g) \bullet (\delta + q') - g \bullet (g \bullet (\delta + q'))$$

$$= (\partial_t^2 g - g \bullet g) \bullet (\delta + q').$$

In the last step we utilized the associativity property $g \bullet (g \bullet q') = (g \bullet g) \bullet q'$ which is equivalent to the relabelling $\int_{\mathbb{R}} g(x,z;t) \int_{\mathbb{R}} g(z,\zeta;t) q'(\zeta,y;t) \, d\zeta \, dz = \int_{\mathbb{R}} \int_{\mathbb{R}} g(x,\zeta;t) g(\zeta,z;t) \, d\zeta \, q'(z,y;t) \, dz$. We now equivalence by $Q = Q(t)$, i.e. post-compose by $Q := Q^{-1}$. This is equivalent to “multiplying” the equation above by $\bullet (\delta + \tilde{q})$ where $(\delta + \tilde{q}) \bullet (\delta + \tilde{q}) = \delta$ and $\tilde{q}$ is the integral kernel associated with $Q - \text{id}$. We thus observe that $g = g(x,y;t)$ necessarily satisfies the nonlocal nonlinear partial differential equation

$$
\partial_t g = \partial_t^2 g - g \bullet g
$$

or more explicitly

$$
\partial_t g(x,y;t) = \partial_t^2 g(x,y;t) - \int_{\mathbb{R}} g(x,z;t) g(z,y;t) \, dz.
$$
Further now suppose, given initial data $g(x, y; 0) = g_0(x, y)$ we wish to solve this nonlocal nonlinear partial differential equation. We observe that we can explicitly solve, in closed form via Fourier transform, for $p = p(x, y; t)$ and then $q' = q'(x, y; t)$. We take $q'(x, y; 0) = 0$ and $p(x, y; 0) = g_0(x, y)$. This choice is consistent with the Riccati relation evaluated at time $t = 0$. Then the solution of the Riccati relation by iteration or other means, and in some cases explicitly, generates the solution $g = g(x, y; t)$ to the nonlocal nonlinear partial differential equation above corresponding to the initial data $g_0$. We have thus now seen the “abstract” setting and the connection to nonlocal nonlinear partial differential equations and their solution, and thus started to lay the foundations to validating our claims at the very beginning of this introduction.

The approach we have outlined above, for us, has its roots in the series of papers in numerical spectral theory in which Riccati equations were derived and solved in order to resolve numerical difficulties associated with linear spectral problems. These difficulties were associated with different exponential growth rates in the far-field. See for example Ledoux, Malham and Thömmel [21], Ledoux, Malham, Niesen and Thömmel [20], Karambal and Malham [18] and Beck and Malham [6] for more details of the use of Riccati equations and Grassmann flows to help numerically evaluate the pure-point spectra of linear elliptic operators. In Beck et al. [5] we turned the question around and asked whether the Riccati equations, which in infinite dimensions represent nonlinear partial differential equations, could be solved by the reverse process.

The notion that integrable nonlinear partial differential equations can be generated from solutions to the corresponding linearized equation and a linear integral equation, namely the Gel’fand–Levitan–Marchenko equation, goes back over forty years. For example it is mentioned in the review by Miura [24]. Dyson [14] in particular showed the solution to the Korteweg de Vries equation can be generated from the solution to the Gel’fand–Levitan–Marchenko equation along the diagonal. See for example Drazin and Johnson [12, p. 86]. Further results of this nature for other integrable systems are summarized in Ablowitz, Ramani and Segur [1]. Then through a sequence of papers Pöppe [25–27], Pöppe and Sattinger [28] and Bauhardt and Pöppe [3], carried through the programme intimated above. Also in a series of papers Tracy and Widom, see for example [36], have also generated similar results. Besides those already mentioned, the papers by Sato [32,33], Segal and Wilson [34], Wilson [38], Bornemann [8], McKea [19], Grellier and Gerard [15] and Beals and Coifman [4], as well as the manuscript by Guest [16] were also highly influential in this regard.

We note that our second prescription above is analogous to that of classical integrable systems and the Darboux-dressing transformation. The notion of classical integrability in $1 + 1$ dimensions is synonymous with the existence of a Lax pair ($\hat{L}, \hat{D}$). The Lax pair may consist of differential operators depending on the field, i.e. the solution of the associated nonlinear integrable partial differential equation, or field valued matrices, which can also depend on a
Partially differential systems with nonlocal nonlinearities

The spectral parameter. The Lax pair satisfies the so-called auxiliary linear problem

$$\tilde{L} \Psi = \lambda \Psi$$

and

$$\partial_t \Psi = \tilde{D} \Psi.$$ 

Here $\Psi$ is called the auxiliary function and $\lambda$ is the spectral parameter which is constant in time. Compatibility between the two equations above leads to the zero curvature condition

$$\partial_t \tilde{L} = [\tilde{D}, \tilde{L}],$$

which generates the nonlinear integrable equation. The Darboux-dressing transformation is an efficient and elegant way to obtain solutions of the integrable equation using linear data; see Matveev & Salle [23] and Zakharov & Shabat [39]. Let us focus on the $t$-part of the auxiliary linear problem to make the connection with our present formulation more concrete. In the context of integrable systems, the Darboux-dressing prescription takes the form of a: (i) Base equation or linearized formulation: $\partial_t P = DP$; (ii) Auxiliary or modified or dressed equation: $\partial_t Q = \tilde{D}Q$; and (iii) Riccati relation or dressing transformation: $P = GQ$. In the integrable systems frame $D$ is a linear differential operator and $\tilde{D}$ is a nonlinear differential operator that can be determined via the dressing process; see Zakharov & Shabat [39] and Drazin and Johnson [12]. The classic example is the Korteweg de Vries equation, in which case $D = -4\partial_x^3$ and $\tilde{D} = -4\partial_x^3 + 6u(x, t)\partial_x^2 + \partial_x u(x, t)$. In the integrability context extra symmetries and thus integrability is provided by the existence of the operator $\tilde{L}$ of the Lax pair. For the Korteweg de Vries equation $\tilde{L} = -\partial_x^2 + u(x, t)$. That the field $u$ satisfies the Korteweg de Vries equation is ensured by the zero curvature condition. In our formulation on the other hand, we do not assume the existence of a Lax pair as we do not necessarily require integrability, thus less symmetry is presupposed. We focus on the time part of the Darboux transform described by the equations (i)–(iii) just above. They yield the equation for the transformation $G$ (see also Adamopoulou, Doikou & Papamikos [2]):

$$\partial_t G = DG - G \tilde{D}.$$ 

In the present general description the operators $D$ and $\tilde{D}$ are known and both linear; at least in all the examples we consider herein. The operator $G$ turns out to satisfy the associated nonlinear and nonlocal partial differential equation just above. Depending on the exact form of $\tilde{D}$ various cases of nonlinearity can be considered as will be discussed in detail in what follows. Indeed, below we investigate various situations regarding the form of the nonlinear operator $\tilde{D}$, which give rise to qualitatively different nonlocal, nonlinear equations. These can be seen as nonlocal generalizations of well-known examples of integrable equations, such as the Korteweg de Vries and nonlinear Schrödinger equations and so forth.

Lastly, we remark that Riccati systems play a central role in optimal control theory. In particular, the solution to a matrix Riccati equation provides the optimal continuous feedback operator in linear-quadratic control. In such systems the state is governed by a linear system of equations analogous to
those for $Q$ and $P$ above, and the goal is to optimize a given quadratic cost function. See for example Martin and Hermann [22], Brockett and Byrnes [10] and Hermann and Martin [17] for more details.

Our paper is structured as follows. In §2 we outline our procedure for generating solutions to partial differential systems with quadratic nonlocal nonlinearities from the corresponding linearized flow. We then examine the slightly modified procedure for generating such solutions for partial differential systems with cubic and higher odd degree nonlocal nonlinearities in §3. In §4 we apply our method to a series of six examples, including a nonlocal reaction-diffusion system, the nonlocal Korteweg de Vries equation and two nonlocal variants of the nonlinear Schrödinger equation, one with cubic nonlinearity and one with a sinusoidal nonlinearity. For each of the examples just mentioned we provide numerical simulations and details of our numerical method. Using our method we also derive an explicit form for solutions to a special case of the nonlocal Fisher–Kolmogorov–Petrovskii–Piskunov equation from biological systems. Finally in §5 we discuss extensions to our method we intend to pursue. We provide the Matlab programs we used for our simulations in the supplementary electronic material.

2 Nonlocal quadratic nonlinearities

In this section we review and at the same time extend to systems our Riccati method for generating solutions to partial differential equations with quadratic nonlocal nonlinearities. For further background details, see Beck et al. [5]. Our basic context is as follows. We suppose we have a separable Hilbert space $H$ that admits a direct sum decomposition $H = Q \oplus P$ into closed subspaces $Q$ and $P$. The set of all subspaces ‘comparable’ in size to $Q$ is called the Fredholm Grassmann manifold $\text{Gr}(H, Q)$. Coordinate patches of $\text{Gr}(H, Q)$ are graphs of operators $Q \rightarrow P$ parametrized by, say, $G$. See Sato [33] and Pressley and Segal [29] for more details.

We consider a linear evolutionary flow on the subspace $Q$ which can be parametrized by two linear operators $Q(t) : Q \rightarrow Q$ and $P(t) : Q \rightarrow P$ for $t \in [0, T]$ for some $T > 0$. More precisely, we suppose the operator $Q = Q(t)$ is a compact perturbation of the identity, and thus a Fredholm operator. Indeed we assume $Q = Q(t)$ has the form $Q = \text{id} + Q'$ where ‘id’ is the identity operator on $Q$. We assume for some $T > 0$ that $Q' \in C^\infty([0, T]; \mathcal{J}_2(Q; Q))$ and $P \in C^\infty([0, T]; \mathcal{J}_2(Q; P))$ where $\mathcal{J}_2(Q; Q)$ and $\mathcal{J}_2(Q; P)$ denote the class of Hilbert–Schmidt operators from $Q \rightarrow Q$ and $Q \rightarrow P$, respectively. Note that $\mathcal{J}_2(Q; Q)$ and $\mathcal{J}_2(Q; P)$ are Hilbert spaces. Our analysis, as we see presently, involves two, in general unbounded, linear operators $D$ and $B$. In our equations these operators act on $P$, and since for each $t \in [0, T]$ we would like $DP \in \mathcal{J}_2(Q; P)$ and $BP \in \mathcal{J}_2(Q; Q)$, we will assume that $P \in C^\infty([0, T]; \text{Dom}(D) \cap \text{Dom}(B))$. Here $\text{Dom}(D) \subseteq \mathcal{J}_2(Q; P)$ and $\text{Dom}(B) \subseteq \mathcal{J}_2(Q; P)$ represent the domains of $D$ and $B$ in $\mathcal{J}_2(Q; P)$. Hence in summary, we assume

\[ P \in C^\infty([0, T]; \text{Dom}(D) \cap \text{Dom}(B)) \quad \text{and} \quad Q' \in C^\infty([0, T]; \mathcal{J}_2(Q; Q)). \]
Our analysis also involves two bounded linear operators \( A = A(t) \) and \( C = C(t) \). Indeed we assume that \( A \in C^\infty([0, T]; \mathcal{L}_2(\mathbb{Q}; \mathbb{Q})) \) and \( C \in C^\infty([0, T]; \mathcal{L}_2(\mathbb{Q}; \mathbb{P})) \). We are now in a position to prescribe the evolutionary flow of the linear operators \( Q = Q(t) \) and \( P = P(t) \) as follows.

**Definition 1 (Linear Base and Auxiliary Equations)** We assume there exists a \( T > 0 \) such that, for the linear operators \( A, B, C \) and \( D \) described above, the linear operators \( P \in C^\infty([0, T]; \text{Dom}(D) \cap \text{Dom}(B)) \) and \( Q' \in C^\infty([0, T]; \mathcal{L}_2(\mathbb{Q}; \mathbb{Q})) \) satisfy the linear system of operator equations

\[
\partial_t Q = A Q + B P, \quad \text{and} \quad \partial_t P = C Q + D P,
\]

where \( Q = \text{id} + Q' \). We take \( Q'(0) = O \) at time \( t = 0 \) so that \( Q(0) = \text{id} \). We call the evolution equation for \( P = P(t) \) the **base equation** and the evolution equation for \( Q = Q(t) \) the **auxiliary equation**.

**Remark 1** We note the following: (i) **Nomenclature:** The base and auxiliary equations above are a coupled pair of linear evolution equations for the operators \( P = P(t) \) and \( Q = Q(t) \). In many applications and indeed for all those in this paper \( C = O \). In this case the equation for \( P = P(t) \) collapses to the stand alone equation \( \partial_t P = DP \). For this reason we call it the base equation and we think of the equation prescribing the evolution of \( Q = Q(t) \) as the auxiliary equation; and (ii) **In practice:** In all our examples in §4 we can solve the base and auxiliary equations for \( P = P(t) \) and \( Q = Q(t) \) giving explicit closed form solution expressions for all \( t \geq 0 \).

In addition to the linear base and auxiliary equations above, we posit a linear relation between \( P = P(t) \) and \( Q = Q(t) \) as follows.

**Definition 2 (Riccati relation)** We assume there exists a \( T > 0 \) such that, for \( P \in C^\infty([0, T]; \text{Dom}(D) \cap \text{Dom}(B)) \) and \( Q' \in C^\infty([0, T]; \mathcal{L}_2(\mathbb{Q}; \mathbb{Q})) \), there exists a linear operator \( G \in C^\infty([0, T]; \text{Dom}(D) \cap \text{Dom}(B)) \) satisfying the linear Fredholm equation

\[
P = G Q,
\]

where \( Q = \text{id} + Q' \). We call this the **Riccati relation**.

The existence of a solution to the Riccati relation is governed by the regularized Fredholm determinant \( \det_2(\text{id} + Q') \) for the Hilbert–Schmidt class operator \( Q' = Q'(t) \). For any linear operator \( Q' \in \mathcal{L}_2(\mathbb{Q}; \mathbb{Q}) \) this regularized Fredholm determinant is given by (see Simon [35] and Reed and Simon [31])

\[
\det_2(\text{id} + Q') := \exp \left( \sum_{\ell \geq 2} \frac{(-1)^{\ell-1}}{\ell} \text{tr} (Q')^\ell \right),
\]

where ‘tr’ represents the trace operator. We note that \( \|Q'\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})}^2 = \text{tr} |Q'|^2 \). The operator \( \text{id} + Q' \) is invertible if and only if \( \det_2(\text{id} + Q') \neq 0 \); again see Simon [35] and Reed and Simon [31] for more details.
Lemma 1 (Existence and Uniqueness: Riccati relation) Assume there exists a $T > 0$ such that $P \in C^\infty([0,T];\text{Dom}(D) \cap \text{Dom}(B))$, $Q' \in C^\infty([0,T];\mathcal{L}_2(\mathbb{Q}; \mathbb{Q}))$ and $Q(0) = O$. Then there exists a $T' > 0$ with $T' \leq T$ such that for $t \in [0,T']$ we have $\det_2(\text{id} + Q'(t)) \neq 0$ and $\|Q'(t)\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})} < 1$. In particular, there exists a unique solution $G \in C^\infty([0,T'];\text{Dom}(D) \cap \text{Dom}(B))$ to the Riccati relation.

Proof Since $Q' \in C^\infty([0,T];\mathcal{L}_2(\mathbb{Q}; \mathbb{Q}))$ and $Q(0) = O$, by continuity there exists a $T' > 0$ with $T' \leq T$ such that $\|Q'(t)\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})} < 1$ for $t \in [0,T']$. Similarly by continuity, since $Q'(0) = O$, for a short time at least we expect $\det_2(\text{id} + Q') \neq 0$. We can however assess this as follows. Using the regularized Fredholm determinant formula above, we observe that

$$\left| \det_2(\text{id} + Q') - 1 \right| \leq \sum_{n \geq 1} \frac{1}{n!} \left( \sum_{\ell \geq 2} \frac{1}{\ell} \text{tr} |Q'|^\ell \right) \leq \exp \left( \sum_{\ell \geq 2} \frac{1}{\ell} \|Q\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})}^\ell \right) - 1.$$

In the last step we used that $\text{tr} |Q'|^\ell \leq (\text{tr} |Q'|^2)^{\ell/2}$ for all $\ell \geq 2$. The series in the exponent in the final term above converges if $\|Q\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})} < 1$. We deduce that provided $\|Q\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})}$ is sufficiently small then its regularized Fredholm determinant is bounded away from zero. By continuity there exists a $T'$, possibly smaller than the choice above, such that for all $t \in [0,T']$ we know $\|Q'(t)\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})}$ is sufficiently small and the determinant is bounded away from zero.

Next, we set $\|H\|_{\text{Dom}(D) \cap \text{Dom}(B)} := \|DH\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})} + \|BH\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})}$ for any $H \in \text{Dom}(D) \cap \text{Dom}(B)$, while $\| \cdot \|_{\text{op}}$ denotes the operator norm for bounded operators on $\mathbb{Q}$. We observe that for any $n \in \mathbb{N}$ we have

$$\left\| P(t)(Q'(t))^n \right\|_{\text{Dom}(D) \cap \text{Dom}(B)} \leq \|P(t)\|_{\text{Dom}(D) \cap \text{Dom}(B)} \|Q'(t)^n\|_{\text{op}} \leq \|P(t)\|_{\text{Dom}(D) \cap \text{Dom}(B)} \|Q'(t)^n\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})} \leq \|P(t)\|_{\text{Dom}(D) \cap \text{Dom}(B)} \|Q'(t)^n\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})}.$$

Hence we observe that

$$\left\| P(t) \left( \sum_{n \geq 1} (-1)^n (Q'(t))^n \right) \right\|_{\text{Dom}(D) \cap \text{Dom}(B)} \leq \|P(t)\|_{\text{Dom}(D) \cap \text{Dom}(B)} \left( 1 + \sum_{n \geq 1} \|Q'(t)^n\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})} \right) \leq \|P(t)\|_{\text{Dom}(D) \cap \text{Dom}(B)} \left( 1 - \|Q'(t)\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})} \right)^{-1}.$$

Hence using the operator series expansion for $(\text{id} + Q'(t))^{-1}$ we observe we have established that

$$\left\| P(t)(\text{id} + Q'(t))^{-1} \right\|_{\text{Dom}(D) \cap \text{Dom}(B)} \leq \|P(t)\|_{\text{Dom}(D) \cap \text{Dom}(B)} \left( 1 - \|Q'(t)\|_{\mathcal{L}_2(\mathbb{Q}; \mathbb{Q})} \right)^{-1}.$$

Hence there exists a $T' > 0$ such that for each $t \in [0,T']$ we know $G(t) = P(t)(\text{id} + Q'(t))^{-1}$ exists, is unique, and in fact $G \in C^\infty([0,T'];\text{Dom}(D) \cap \text{Dom}(B))$. \qed
Remark 2 (Initial data) We have already remarked that we set $Q'(0) = O$ so that $Q(0) = \text{id}$. Consistent with the Riccati relation we hereafter set $P(0) = G(0)$.

Our first main result in this section is as follows.

Theorem 1 (Quadratic Degree Evolution Equation) Given initial data $G_0 \in \text{Dom}(D) \cap \text{Dom}(B)$ we set $Q'(0) = O$ and $P(0) = G_0$. Suppose there exists a $T > 0$ such that the linear operators $P \in C^\omega([0, T]; \text{Dom}(D) \cap \text{Dom}(B))$ and $Q' \in C^\omega([0, T]; \mathcal{B}_2(\mathbb{R}; \mathbb{Q}))$ satisfy the linear base and auxiliary equations. We choose $T > 0$ so that for $t \in [0, T]$ we have $\det_2(\text{id} + Q'(t)) \neq 0$ and $\|Q'(t)\|_{\mathcal{B}_2(\mathbb{R}; \mathbb{Q})} < 1$. Then there exists a unique solution $G \in C^\omega([0, T]; \text{Dom}(D) \cap \text{Dom}(B))$ to the Riccati relation which necessarily satisfies $G(0) = G_0$ and the Riccati evolution equation

$$\dot{G} = C + DG - G(A + BG).$$

Proof By direct computation, differentiating the Riccati relation $P = GQ$ with respect to time using the product rule, using the base and auxiliary equations and feeding back through the Riccati relation, we find $(\dot{G})Q = \dot{G}P - G\dot{G}Q = (C + DG)Q - (G(A + BG))Q$. Equivalencing with respect to $Q$, i.e. postcomposing by $Q^{-1}$, establishes the result. \qed

Remark 3 We assume throughout this paper that $C = C(t)$ is a bounded operator, indeed that $C \in C^\omega([0, T]; \mathcal{B}_2(\mathbb{R}; \mathbb{P}))$. In fact in every application in §4 we take $C = 0$. However in general $C = C(t)$ would represent some non-homogeneous forcing in the Riccati equation satisfied by $G = G(t)$. Further, in Doikou, Malham & Wiese [11] we apply our methods here to stochastic partial differential equations. One example therein features additive space-time white noise. In that case the term $C = C(t)$ represents the non-homogenous space-time white noise forcing term and we must thus allow for $C = C(t)$ to be an unbounded operator.

We now turn our attention to applications of Theorem 1 above and demonstrate how to find solutions to a large class of partial differential systems with nonlocal quadratic nonlinearities. Guided by our results above, we now suppose the classes of operators we have considered thusfar to be those with integral kernels on $\mathbb{R} \times \mathbb{R}$. For $x, y \in \mathbb{R}$ and $t \geq 0$, suppose the functions $p = p(x, y; t)$ and $q' = q'(x, y; t)$ are matrix valued, with $p \in \mathbb{R}^{n \times n}$ and $q' \in \mathbb{R}^{n \times n}$ for some $n, n' \in \mathbb{N}$, and they satisfy the linear base and auxiliary equations

$$\dot{p}(x, y; t) = d(\hat{c}_1) p(x, y; t) \quad \text{and} \quad \dot{q}'(x, y; t) = b(x) p(x, y; t).$$

Here the unbounded operator $d = d(\hat{c}_1)$ is a constant coefficient scalar polynomial function of the partial differential operator with respect to the first component $\hat{c}_1$, while $b = b(x)$ is a smooth bounded square-integrable $\mathbb{R}^{n \times n'}$-valued function of $x \in \mathbb{R}$. We can explicitly solve these equations for $p = p(x, y; t)$ and $q' = q'(x, y; t)$ in terms of their Fourier transforms as follows. Note we use the
following notation for the Fourier transform of any function $f = f(x,y)$ and its inverse:

$$\hat{f}(k,\kappa) := \int_{\mathbb{R}^2} f(x,y) e^{2\pi i (kx + \kappa y)} \, dx \, dy$$

and

$$f(x,y) := \int_{\mathbb{R}^2} \hat{f}(k,\kappa) e^{-2\pi i (kx + \kappa y)} \, dk \, d\kappa.$$ 

**Lemma 2** Let $\hat{p} = \hat{p}(k,\kappa; t)$ and $\hat{q} = \hat{q}(k,\kappa; t)$ denote the two-dimensional Fourier transforms of the solutions to the linear base and auxiliary equations just above. Assume that $q'(x,y;0) = 0$ and $p(x,y;0) = p_0(x,y)$. Then for all $t \geq 0$ the functions $\hat{p}$ and $\hat{q}$ are explicitly given by

$$\hat{p}(k,\kappa; t) = \exp\left(d(2\pi i k) t\right) \hat{p}_0(k,\kappa)$$

and

$$\hat{q}(k,\kappa; t) = \int_{\mathbb{R}} \hat{b}(k - \lambda) \hat{I}(\lambda; t) \hat{p}_0(\lambda,\kappa) \, d\lambda,$$

where $\hat{I}(k; t) := \left(\exp\left(d(2\pi i k) t\right) - 1\right) / (d(2\pi i k))$ and indeed $q'(x,y; t) = b(x) \int_{\mathbb{R}} I(x-z, t) p_0(z,y) \, dz$.

**Proof** Taking the two-dimensional Fourier transform of the base equation we generate the decoupled equation $\hat{\partial}_t \hat{p}(k,\kappa; t) = d(2\pi i k) \hat{p}(k,\kappa; t)$ whose solution is the form for $\hat{p}(k,\kappa; t)$ shown. Then take the Fourier transform of the auxiliary equation to generate the equation $\hat{\partial}_t \hat{q}(k,\kappa; t) = \int_{\mathbb{R}} \hat{b}(k - \lambda) \hat{p}(\lambda,\kappa; t) \, d\lambda$. Substituting in the explicit form for $\hat{p} = \hat{p}(k,\kappa; t)$ and integrating with respect to time, using $\hat{q}(k,\kappa; 0) = 0$, generates the form for $\hat{q}' = \hat{q}'(k,\kappa; t)$ shown. □

**Remark 4 (Hilbert–Schmidt solutions)** We suppose here the separable Hilbert space $\mathbb{H} = L^2(\mathbb{R}; \mathbb{R}^n) \times (\text{Dom}(D) \cap \text{Dom}(B))$ with $\text{Dom}(D) \cap \text{Dom}(B) \subseteq L^2(\mathbb{R}; \mathbb{R}^n)$ where $n$ and $n'$ are the dimensions above. Then $P$ and $Q$ are closed subspaces in the direct sum decomposition $\mathbb{H} = Q \oplus P$; see Beck et al. [5]. The functions in $Q$ are $\mathbb{R}^n$-valued while those in $P$ are $\mathbb{R}^{n'}$-valued. By standard theory, $Q'(t) \in L^2(\mathbb{R}; Q)$ and $P(t) \in L^2(\mathbb{R}; P)$ if and only if there exist kernel functions $q'(\cdot,\cdot; t) \in L^2(\mathbb{R}^2; \mathbb{R}^{n \times n})$ and $p(\cdot,\cdot; t) \in L^2(\mathbb{R}^2; \mathbb{R}^{n' \times n})$ with the action of $Q'(t)$ and $P(t)$ given through $q'$ and $p$, respectively. Further we know that $\|Q'(t)\|_{L^2(\mathbb{R}; Q)} = \|q'(\cdot,\cdot; t)\|_{L^2(\mathbb{R}^2; \mathbb{R}^{n \times n})}$ and $\|P(t)\|_{L^2(\mathbb{R}; P)} = \|p(\cdot,\cdot; t)\|_{L^2(\mathbb{R}^2; \mathbb{R}^{n' \times n})}$. For more details see for example Reed & Simon [30, p. 210] or Karambal & Malham [18]. The linear base and auxiliary equations above correspond to the case when $A = C = O$, $D = d(\partial_1)$ and $B$ is given by the bounded multiplicative operator $b = b(x)$. Recall that in our “abstract” formulation above we required that $P \in C^{\infty}(\{0, T\}; \text{Dom}(D) \cap \text{Dom}(B))$. The explicit form for $p = p(x,y; t)$ given in Lemma 2 reveals that $P$ will only have this property for certain classes of operators $d = d(\partial_1)$. For example suppose $d = d(\partial_1)$ is diffusive so that it takes the form of a polynomial with only even
degree terms in \( \hat{\partial}_1 \) and the real scalar coefficient of the degree 2\( N \) term is of the form \((-1)^{N+1}a_{2N}\). In this case the exponential term \( \exp(d(2\pi ik)t) \) decays exponentially for all \( t > 0 \). We could also include dispersive forms for \( d \). For example \( d = \hat{\partial}_1^2 \), for which the exponential term \( \exp(d(2\pi ik)t) \) remains bounded for all \( t > 0 \). We also note that for such diffusive or dispersive forms for \( d = d(\hat{\partial}_1^2) \) the integral kernel function \( p = p(x, y; t) \) is in fact smooth. Also recall from our “abstract” formulation we require \( Q' \in C^\infty([0, t]; \mathbb{R}^2; \mathbb{Q}) \). The explicit form for \( q' = q'(x, y; t) \) given in Lemma 2 reveals that its time dependence is characterized through the term \( \hat{I}(k; t) \). For the diffusive or dispersive forms for \( d = d(\hat{\partial}_1^2) \) just discussed we observe that \( \hat{I}(k; t) \to -1/(2\pi ik) \) for all \( k \neq 0 \) while for the singular value \( k = 0 \) the term \( \hat{I}(0; t) \) grows linearly in time. Thus in such cases, while we know that for some time \( T > 0 \) for \( t \in [0, T] \) we have \( \|Q'(t)\|_{\mathcal{D}_2(\mathbb{Q}; \mathbb{Q})} = \|q'(; \cdot; t)\|_{L^2(\mathbb{R}^2; \mathbb{R}^{n \times n'})} = \|q'(; \cdot; t)\|_{L^2(\mathbb{R}^2; \mathbb{C}^{n \times n})} \) is bounded, we also have

\[
\||\hat{I}(t)\||_{L^1(\mathbb{R}; \mathbb{C})} \text{ bounded for all } t > 0, \text{ then } \|q'(\cdot; t)\|_{L^2(\mathbb{R}^2; \mathbb{C}^{n \times n})}\]

for all \( t > 0 \), and indeed smooth. However how far the interval of time on which \( \det_2(Id + Q'(t)) \neq 0 \) and \( \|Q'(t)\|_{\mathcal{D}_2(\mathbb{Q}; \mathbb{Q})} < 1 \) extends, for now, we treat on case by case basis.

**Corollary 1 (Evolutionary PDEs with quadratic nonlocal nonlinearities)** Given initial data \( g_0 \in C^\infty(\mathbb{R}^2; \mathbb{R}^{n \times n'}) \cap L^2(\mathbb{R}^2; \mathbb{R}^{n \times n}) \) for some \( n, n' \in \mathbb{N} \), suppose \( p = p(x, y; t) \) and \( q' = q'(x, y; t) \) are the solutions to the linear base and auxiliary equations from Lemma 2 for which \( p_0 \equiv g_0 \) and \( q'(x, y; 0) \equiv 0 \). Let \( \text{Dom}(d) \) denote the domain of the operator \( d = d(\hat{\partial}_1^2) \) and suppose it is of the diffusive or dispersive form described in Remark 4. Then there exists a \( T > 0 \) such that the solution \( g \in C^\infty([0, T]; \text{Dom}(d) \cap L^2(\mathbb{R}^2; \mathbb{R}^{n \times n'})) \) to the linear Fredholm equation

\[
p(x, y; t) = g(x, y; t) + \int_{\mathbb{R}} g(x, z; t) q'(z, y; t) \, dz
\]

solves the evolutionary partial differential equation with quadratic nonlocal nonlinearities of the form

\[
\hat{\partial}_1 g(x, y; t) = d(\hat{\partial}_2) g(x, y; t) - \int_{\mathbb{R}} g(x, z; t) b(z) \, g(z, y; t) \, dz.
\]
Proof That for some $T > 0$ there exists a solution $g \in C^\infty([0,T];\text{Dom}(d) \cap L^2(\mathbb{R}^2;\mathbb{R}^{n \times n}))$ to the linear Fredholm equation (Riccati relation) shown is a consequence of Lemma 1 and Remark 4. The solution $g$ is the integral kernel of $G$. That this solution $g$ to the Riccati relation solves the evolutionary partial differential equation with the quadratic nonlocal nonlinearity shown is a direct consequence of the Quadratic Degree Evolution Equation Theorem 1. □

Remark 5 We can also now think of this result in the following way. First differentiate the above linear Fredholm equation in the Corollary with respect to time using the product rule, and use that $p$ and $q_1$ satisfy the linear base and auxiliary equations so that

$$\partial_t g(x, y; t) + \int_{\mathbb{R}} \partial_t g(x, z; t) q'(z, y; t) \, dz = d(\partial_1) p(x, y; t) - \int_{\mathbb{R}} g(x, z; t) b(z)p(z, y; t) \, dz.$$  

Second replacing all instances of $p$ using the linear Fredholm equation above and swapping integration labels we obtain

$$\partial_t g(x, y; t) + \int_{\mathbb{R}} \partial_t g(x, z; t) q'(z, y; t) \, dz = \int_{\mathbb{R}} (\int_{\mathbb{R}} g(x, \zeta; t) b(\zeta) g(\zeta, z) \, d\zeta) q'(z, y; t) \, dz.$$  

We can express this in the form

$$\int_{\mathbb{R}} \left( \partial_t g(x, z; t) - d(\partial_1) g(x, z; t) \right) \, dz + \int_{\mathbb{R}} g(x, \zeta; t) b(\zeta) g(\zeta, z; t) \, d\zeta \right) (\delta(z - y) + q'(z, y; t)) \, dz = 0.$$  

Third we postmultiply by $\delta(y - \eta) + q'(y, \eta; t)'$ for some $\eta \in \mathbb{R}$. This is the kernel corresponding to the inverse operator $\text{id} + Q'$ of $\text{id} + Q$. Integrating over $y \in \mathbb{R}$ gives the result for $g = g(x, \eta; t)$. This derivation follows that in Beck et al. [5] for scalar partial differential equations.

Remark 6 Some observations are as follows: (i) Nonlocal nonlinearities with derivatives: Starting with the linear base and auxiliary equations for $p = p(x, y; t)$ and $q = q'(x, y; t)$, we could have taken $b$ to be any constant coefficient polynomial of $\partial_1$. With minor modifications, all of the main arguments above still apply. Our explicit solution for $q' = q'(x, y; t)$ will be slightly more involved. One of our examples in §4 is the nonlocal Korteweg de Vries
equation for which \( b = \partial_t \); (ii) **Smooth solutions:** All derivatives are with respect to the first parameter \( x \). Differentiating the Riccati relation gives
\[
\partial_x p(x, y; t) = \partial_x g(x, y; t) + \int_\mathbb{R} \partial_z g(x, z; t) q'(z, y; t) \, dz.
\]
Hence the regularity of the solution \( g \) is directly determined by the regularity of the solution of the base equation \( p \) for the time the Riccati relation is solvable, in particular while \( \det_2 (\mathrm{id} + Q'(t)) \neq 0 \) and \( \|Q'(t)\|_{L_2(\mathbb{R}; \mathbb{Q})} < 1 \). Hence if \( p \) is smooth on this interval, then the solution \( g \) is smooth on this interval; (iii) **Time as a parameter:** Importantly, when we can explicitly solve for \( p = p(x, y; t) \) and \( q' = q'(x, y; t) \), we choose the parameter \( t \) at which we wish to compute the solution and we solve the linear Fredholm equation to generate the solution \( g \) for that time \( t \); (iv) **Non-homogeneous coefficients:** In principle, if \( d \) and \( b \) are polynomials of \( \partial_x \), the coefficients in these polynomial could also be functions of \( x \). Though we can in principle always find series solutions to the linear base and auxiliary equations, we would now have the issue as to whether we can derive explicit formulae for \( p \) and \( q' \). In such cases we may need to evaluate a series or numerically integrate in time to obtain \( p \) and \( q' \). Thus we cannot compute solutions as simply as in the sense outlined in Item (iii) just above. An important example is that of evolutionary stochastic partial differential equations with non-local nonlinearities. The presence of Wiener fields in such equations as non-homogeneous additive terms or multiplicative factors means that the base equation must be solved numerically. For example the base equation might be the stochastic heat equation. See Doikou, Malham & Wiese [11] for more details; (v) **Complex valued solutions:** In general \( g \) could be complex matrix valued; see §3 next; (vi) **Domains:** If \( x, y \in \mathbb{I} \) where \( \mathbb{I} \) is a finite or semi-infinite interval on \( \mathbb{R} \), then the above calculations go through, see Beck et al. [5] and also Doikou et al. [11] where \( \mathbb{I} = \mathbb{T} \), the torus with period \( 2\pi \); and (vii) **Multi-dimensional domains:** If \( x, y \in \mathbb{R}^n \) for some \( n \in \mathbb{N} \) and \( d = d(\Delta_1) \) is a polynomial function of the Laplacian acting on the first argument, then in principle the calculations above go through; see our Conclusions §5.

### 3 Nonlocal cubic and higher odd degree nonlinearities

We assume the same set-up as in the first two paragraphs in §2 up to the point when we discuss the unbounded linear operator \( D \). In this section we assume \( \mathbb{P} \subseteq \mathbb{Q} \). We still assume that \( D \) is in general an unbounded, linear operator, however we set \( B = O \) and \( C = O \) while \( A \) is a bounded operator which we discuss presently. We assume there exists a \( T > 0 \) such that for each \( t \in [0, T] \) we have \( P \in C^\infty([0, T]; \mathrm{Dom}(D)) \) and \( Q' \in C^\infty([0, T]; \mathcal{S}_2(\mathbb{Q}; \mathbb{Q})) \). Our analysis in this section also involves the bounded linear operator \( A \in \mathcal{S}_2(\mathbb{Q}; \mathbb{Q}) \) which depends on another bounded linear operator as follows. For a known operator \( H \in \mathcal{S}_2(\mathbb{Q}; \mathbb{P}) \) we assume \( A \) has the form \( A = f(\mathbb{H}^\dagger) \) where the function \( f \) is given by
\[
f(x) = \sum_{m \geq 0} \alpha_m x^m,
\]
where $i = \sqrt{-1}$ and the $\alpha_m$ are real coefficients. Note $H^\dagger$ denotes the operator adjoint to $H$. We further assume this power series expansion has an infinite radius of convergence. In this section we assume the evolutionary flow of the linear operators $Q = Q(t)$ and $P = P(t)$ is as follows.

**Definition 3 (Linear Base and Auxiliary Equations (modified))** We assume there exists a $T > 0$ such that for the linear operators $A$ and $D$ described above, the linear operators $P \in C^\infty([0,T];\text{Dom}(D))$ and $Q' \in C^\infty([0,T];\mathcal{H}_2(Q;\mathbb{Q}))$ satisfy the linear system of operator equations

$$\hat{\partial}_t P = D P, \quad \text{and} \quad \hat{\partial}_t Q = f(PP^\dagger)Q,$$

where $Q = \text{id} + Q'$. We take $Q'(0) = O$ at time $t = 0$ so that $Q(0) = \text{id}$. We call the evolution equation for $P = P(t)$ the base equation and the evolution equation for $Q = Q(t)$ the auxiliary equation.

**Remark 7** Note we first solve the base equation for $P \in C^\infty([0,T];\text{Dom}(D))$. Then with $P$ given, we observe that $f = f(PP^\dagger)$ is a given linear operator in the auxiliary equation.

**Lemma 3** Assume for some $T > 0$ that $P \in C^\infty([0,T];\text{Dom}(D))$ and $Q' \in C^\infty([0,T];\mathcal{H}_2(Q;\mathbb{Q}))$ satisfy the linear base and auxiliary equations above. Then $Q(0) = \text{id}$ implies $QQ^\dagger = \text{id}$ for all $t \in [0,T]$.

**Proof** By definition $f^\dagger = -f$, and using the product rule $\hat{\partial}_t (QQ^\dagger) = f(QQ^\dagger) - (QQ^\dagger) f$. Thus $QQ^\dagger = \text{id}$ is a fixed point of this flow and $Q(0) = \text{id}$ implies $QQ^\dagger = \text{id}$ for all $t \in [0,T]$. \hfill $\Box$

In addition to the linear base and auxiliary equations above, we again posit a linear relation between $P = P(t)$ and $Q = Q(t)$, the Riccati relation $P = GQ$, exactly as in §2. Indeed the results of Lemma 1 for the existence and uniqueness of a solution $G$ to the Riccati relation apply here. Further, as previously, hereafter we set $P(0) = G(0)$. Our main result of this section is as follows.

**Theorem 2 (Odd Degree Evolution Equation)** Given initial data $G_0 \in \text{Dom}(D)$ we set $Q(0) = \text{id}$ and $P(0) = G_0$. Suppose there exists a $T > 0$ such that the linear operators $P \in C^\infty([0,T];\text{Dom}(D))$ and $Q - \text{id} \in C^\infty([0,T];\mathcal{H}_2(Q;\mathbb{Q}))$ satisfy the linear base and auxiliary equations above. We choose $T > 0$ so that for $t \in [0,T]$ we have $\text{det}_2(Q(t)) \neq 0$ and $|Q'(t)|_{\mathcal{H}_2(Q;\mathbb{Q})} < 1$. Then there exists a unique solution $G \in C^\infty([0,T];\text{Dom}(D))$ to the Riccati relation which necessarily satisfies the evolution equation

$$\hat{\partial}_t G = DG - G f(GG^\dagger).$$

**Proof** First, using the Riccati relation and that $QQ^\dagger = \text{id}$, we have $PP^\dagger = GG^\dagger$ and thus $f(PP^\dagger) = f(GG^\dagger)$ for all $t \in [0,T]$. Second, differentiating the Riccati relation with respect to time using the product rule and then substituting for $P$ using the Riccati relation, we have $(\hat{\partial}_t G)Q = \hat{\partial}_t P - G \hat{\partial}_t Q = DGQ - G f(PP^\dagger)Q = DGQ - G f(GG^\dagger)Q$. As previously, equivalencing by $Q$, i.e. postcomposing by $Q^{-1}$, establishes the result. \hfill $\Box$
We now consider applications of Theorem 2 above and demonstrate how to find solutions to classes of partial differential systems with nonlocal odd degree nonlinearities. For \( x, y \in \mathbb{R} \) and \( t \geq 0 \), suppose the functions \( p = p(x, y; t) \) and \( q = q(x, y; t) \) are scalar complex valued, with \( p \in \mathbb{C} \) and \( q \in \mathbb{C} \), and they satisfy the linear base and auxiliary equations

\[
\hat{c}_t p = -i h(\hat{c}_1) p \quad \text{and} \quad \hat{c}_t q = f^*(p \ast p^\dagger) \ast q.
\]

Here \( h = h(\hat{c}_1) \) is a polynomial function of \( \hat{c}_1 \) with only even degree terms of its argument and constant coefficients. By analogy with §2, here we have made the choice \( d(\hat{c}_1) = -ih(\hat{c}_1) \). The nonlocal product \( \ast \) is defined for any two functions \( w, w' \in L^2(\mathbb{R}^2; \mathbb{C}) \) by

\[
(w \ast w')(x, y) := \int_{\mathbb{R}} w(x, z) w'(z, y) \, dz.
\]

Hence the expression \( p \ast p^\dagger \) thus represents the kernel function

\[
(p \ast p^\dagger)(x, y; t) := \int_{\mathbb{R}} p(x, z; t)p^*(y, z; t) \, dz,
\]

Note here we have used that if an operator has integral kernel \( p = p(x, y; t) \), its adjoint has integral kernel \( p^*(y, x; t) \), where the \( \ast \) in general denotes complex conjugate transpose. The expression \( f^*(c) \), for some kernel function \( c \), represents the series with real coefficients \( \alpha_m \) given by

\[
f^*(c) = i \sum_{m \geq 0} \alpha_m c^{\ast m},
\]

where \( c^{\ast m} \) is the \( m \)-fold product \( c \ast \cdots \ast c \). We assume this power series has an infinite radius of convergence. In the linear auxiliary equation we take \( c = p^\ast p^\dagger \). It is natural to take the Fourier transform of the base and auxiliary equations with respect to \( x \) and \( y \). The corresponding equations for \( \hat{p} = \hat{p}(k, \kappa; t) \) and \( \hat{q} = \hat{q}(k, \kappa; t) \) are

\[
\hat{c}_t \hat{p} = -i h(2\pi i k) \hat{p} \quad \text{and} \quad \hat{c}_t \hat{q} = \hat{f}^*(\hat{p} \ast \hat{p}^\dagger) \ast \hat{q}.
\]

Here we have used Parseval’s identity for Fourier transforms which implies

\[
(w \ast w')(k, \kappa) = \int_{\mathbb{R}} w(k, \lambda) \hat{w}'(\lambda, \kappa) \, d\lambda = (\hat{w} \ast \hat{w}')(k, \kappa)
\]

for any two functions \( w, w' \in L^2(\mathbb{R}^2; \mathbb{C}) \). Hence we see that for \( f^* = f^*(c) \), we have

\[
f^* = i \sum_{m \geq 0} \alpha_m c^{\ast m} \quad \iff \quad \hat{f}^* = i \sum_{m \geq 0} \alpha_m \hat{c}^{\ast m}.
\]

Further we note that if \( q(x, y; t) = \delta(x - y) + q'(x, y; t) \) then \( \hat{q}(k, \kappa; t) = \delta(k - \kappa) + \hat{q}'(k, \kappa; t) \). The Dirac delta function \( \delta \) here also represents the identity with respect to the \( \ast \) product so that for any \( w \in L^2(\mathbb{R}^2; \mathbb{C}) \) we have \( w \ast \delta = \delta \ast w = w \). With all this in hand, we can in fact explicitly solve for \( \hat{p} = \hat{p}(k, \kappa; t) \) and \( \hat{q} = \hat{q}(k, \kappa; t) \) as follows.
Lemma 4 Let \( \hat{\rho} = \hat{\rho}(k, \kappa; t) \) and \( \hat{q} = \hat{q}(k, \kappa; t) \) denote the two-dimensional Fourier transforms of the solutions to the linear base and auxiliary equations just above. Assume that \( q(x, y; 0) = \delta(x - y) \) and \( p(x, y; 0) = p_0(x, y) \). Then for all \( t \geq 0 \) the functions \( \hat{\rho} \) and \( \hat{q} \) are explicitly given by

\[
\hat{\rho}(k, \kappa; t) = \exp\left(-it h(2\pi k)\right) \hat{\rho}_0(k, \kappa),
\]
\[
\hat{q}(k, \kappa; t) = \exp\left(-it h(-2\pi k)\right) \cdot \exp^* \left(t \left( \hat{f}^*(\hat{\rho}_0 \ast \hat{\rho}_0) + \text{ih} \cdot \delta \right) \right)(k, \kappa; t),
\]

where naturally \( \exp^*(c) = \delta + c + \frac{1}{2}c^2 + \frac{1}{6}c^3 + \cdots \).

Proof The explicit form for \( \hat{\rho} = \hat{\rho}(k, \kappa; t) \) follows directly from the Fourier transformed version of the base equation. We now focus on the auxiliary equation. Consider a typical term say \( \hat{c}^m \) in \( \hat{f}^* \), with \( \hat{c} := \hat{\rho} \ast \hat{\rho}^1 \). Using Parseval’s identity the term \( \hat{c}^m = (\hat{\rho} \ast \hat{\rho}^1)^m \) has the explicit form

\[
\hat{c}^m(\nu_0, \nu_m; t) = \int_{\mathbb{R}^{2m-1}} \left( \prod_{j=1}^{m} \hat{\rho}(\nu_{j-1}, \lambda_j; t) \hat{\rho}^*(\nu_j, \lambda_j; t) \right) d\lambda_1 \cdots d\lambda_m d\nu_1 \cdots d\nu_{m-1}.
\]

If we insert the explicit solution for \( \hat{\rho} \) into this expression and use that \( h \) is a polynomial of even degree terms only, we find

\[
\hat{c}^m(\nu_0, \nu_m; t) = \exp\left(-it \left( h(2\pi \nu_0) - h(-2\pi \nu_m) \right) \right) \times \int_{\mathbb{R}^{2m-1}} \left( \prod_{j=1}^{m} \hat{\rho}_0(\nu_{j-1}, \lambda_j) \hat{\rho}^*_0(\nu_j, \lambda_j) \right) d\lambda_1 \cdots d\lambda_m d\nu_1 \cdots d\nu_{m-1}.
\]

Hence we deduce that

\[
(\hat{f}^*(\hat{\rho} \ast \hat{\rho}^1))(\nu_0, \nu_m; t) = \exp\left(-it \left( h(2\pi \nu_0) - h(-2\pi \nu_m) \right) \right) \left( \hat{f}^*(\hat{\rho}_0 \ast \hat{\rho}_0^1) \right)(\nu_0, \nu_m).
\]

The auxiliary equation thus has the explicit form

\[
\partial_t \hat{q}(k, \kappa; t) = \int_{\mathbb{R}} \exp\left(-it \left( h(2\pi \nu) - h(-2\pi \nu) \right) \right) \left( \hat{f}^*(\hat{\rho}_0 \ast \hat{\rho}_0^1) \right)(k, \nu) \hat{q}(\nu, \kappa; t) d\nu.
\]

By making a change of variables we can convert this linear differential equation for \( \hat{q} = \hat{q}(k, \kappa; t) \) into a constant coefficient linear differential equation. Indeed we set

\[
\tilde{\theta}(k, \kappa; t) := \exp\left(it \left( h(-2\pi k) \right) \right) \hat{q}(k, \kappa; t).
\]

Combining this definition with the linear differential equation for \( \hat{q} = \hat{q}(k, \kappa; t) \) above, we find

\[
\partial_t \tilde{\theta}(k, \kappa; t) = \int_{\mathbb{R}} \left( \hat{f}^*(\hat{\rho}_0 \ast \hat{\rho}_0^1) \right)(k, \nu) \tilde{\theta}(\nu, \kappa; t) d\nu + i h(-2\pi k) \tilde{\theta}(k, \kappa; t),
\]

where, crucially, we again used that \( h(-2\pi k) - h(2\pi k) = 0 \) as \( h \) is a polynomial of even degree terms. Hence the evolution equation for \( \tilde{\theta} \) is the linear constant coefficient equation

\[
\partial_t \tilde{\theta} = \left( \hat{f}^*(\hat{\rho}_0 \ast \hat{\rho}_0^1) + \text{ih} \cdot \delta \right) \ast \tilde{\theta},
\]
Hence if the initial data is smooth, which we assume, so is in Lemma 4, that any Fourier Sobolev norm of the solution at any time

\[ p_t \] equals the corresponding Fourier Sobolev norm of the initial data

\[ p \] only with constant coefficients. Hence and indeed

\[ \frac{\partial}{\partial t} \] and indeed

\[ \delta \] by iteration, can thus be expressed in the form

\[ \delta(k, \kappa; t) = \exp^* \left( t \left( f^* (\hat{p}_0 \ast \hat{p}_0^2) + i h \cdot \delta \right) \right) (k, \kappa; t), \]

where \( \exp^*(c) = \delta + c + \frac{1}{2} c^2 + \frac{1}{6} c^3 + \cdots \). We can recover \( \delta \) from the definition for \( \delta \) above. \( \Box \)

**Remark 8** The iterative procedure alluded to in the proof just above ensures the correct interpretation of the terms in the exponential expansion \( \exp^* \) in the expression for \( \delta = \delta(k, \kappa; t) \) above. Hence for example we have

\[ (\hat{f} + i h \cdot \delta)^* = \hat{f} \ast \hat{f} \ast (i h \cdot \delta) + i h \cdot \hat{f} + (i h) \cdot (i h) \cdot \delta. \]

**Remark 9 (Hilbert–Schmidt solutions)** Here we suppose \( \mathbb{H} = L^2(\mathbb{R}; \mathbb{C}) \times \text{Dom}(D) \) with \( \text{Dom}(D) \subseteq L^2(\mathbb{R}; \mathbb{C}) \) and \( \mathbb{H} = \mathbb{Q} \oplus \mathbb{P} \) with \( \mathbb{P} \) and \( \mathbb{Q} \) closed subspaces of \( \mathbb{H} \); see Beck et al. [5]. The functions in \( \mathbb{Q} \) and \( \mathbb{P} \) are both \( \mathbb{C} \)-valued.

As in Remark 4, with \( Q(t) = \text{id} + Q'(t) \), the operators \( Q'(t) \in \mathfrak{L}(\mathbb{Q}; \mathbb{Q}) \) and \( Q'(t) \in \mathfrak{L}(\mathbb{Q}; \mathbb{P}) \) can be characterized, respectively, by kernel functions

\[ q'(. ; t) \in L^2(\mathbb{R}; \mathbb{C}) \text{ and } p'(. ; t) \in L^2(\mathbb{R}; \mathbb{C}). \]

Further we have the usual isom-etry of Hilbert–Schmidt and \( L^2(\mathbb{R}; \mathbb{C}) \)-norms. The linear base and auxiliary equations for \( p = p(x, y ; t) \) and \( q' = q'(x, y ; t) \) are the versions of the linear base and auxiliary equations in Definition 3 written in terms of their integral kernels; with \( q(x, y ; t) = \delta(x - y) + q' (x, y ; t) \). Note we set \( D = d(\partial^1_1) \) and indeed \( d(\partial^1_1) = -i h(\partial^1_1) \) where \( h \) is a polynomial of even degree terms only with constant coefficients. Hence \( d = d(\partial^1_1) \) is of dispersive form and \( P \in C^\infty([0, T]; \text{Dom}(D)) \) as required in the “abstract” formulation. We observe from the form of the Fourier transform for the solution \( \hat{p} = \hat{p}(k, \kappa; t) \) given in Lemma 4, that any Fourier Sobolev norm of the solution at any time \( t > 0 \) equals the corresponding Fourier Sobolev norm of the initial data \( \hat{p}_0(k, \kappa) \). Hence if the initial data is smooth, which we assume, so is \( p = p(x, y ; t) \) for all \( t > 0 \). Let us now focus on \( q = q(x, y ; t) \) which we recall satisfies the linear auxiliary equation

\[ \hat{q} = \hat{q} \ast \hat{f} \ast (p \ast p^1) \] and the initial condition \( q(x, y ; 0) = \delta(x - y) \).

Since \( p = p(x, y ; t) \) is bounded in any Sobolev norm for all \( t > 0 \), so is \( f^* (p \ast p^1) \).

Let \( p(t) \) denote the function \( \{(x, y) \mapsto p(x, y ; t)\} \), while \( q(t) \) denotes the function \( \{(x, y) \mapsto q(x, y ; t)\} \) and \( \hat{f}(t) \) denotes the function \( \{(x, y) \mapsto f^* (x, y ; t)\} \).

By integrating in time, we can express the linear auxiliary equation in the abstract form

\[ q(t) = \delta + \int_0^t \hat{f}(\tau) \ast q(\tau) \, d\tau. \]
Consequently, for $\rho$ and $\rho'$ in the domain of the operator $d = -i \hbar \hat{c}_1$ where $\hbar = h(\hat{c}_1)$ is defined above, there exists a constant $K > 0$ such that for all $t \in [0, T]$ we have $\|f(t)\|_2 \leq K$, we observe that the $L^2(\mathbb{R}^2; \mathbb{C})$-norm of $(q(t) - \delta)$ is bounded as follows,

$$
\|q(t) - \delta\|^2 \leq \int_0^t \|\hat{f}(\tau)\|^2 \, d\tau + \int_0^t \int_0^\tau \|\hat{f}(\tau) \ast \hat{f}(s)\|^2 \, ds \, d\tau + \cdots \\
\leq \int_0^t \|\hat{f}(\tau)\|^2 \, d\tau + \int_0^t \int_0^\tau \|\hat{f}(\tau)\|^2 \|\hat{f}(s)\|^2 \, ds \, d\tau + \cdots \\
\leq \exp(tK) - 1.
$$

Consequently $|Q'(t)|_2$ is bounded. Further, recalling arguments in the proof of Lemma 1, there exists a $T > 0$ such that for all $t \in [0, T]$ we have $|Q'(t)|_2 < 1$ and $\det_2(id + Q'(t)) \neq 0$.

**Corollary 2 (Evolutionary PDEs with odd degree nonlocal nonlinearities)** Given initial data $g_0 \in C^\infty(\mathbb{R}^2; \mathbb{C}) \cap L^2(\mathbb{R}^2; \mathbb{C})$, suppose $p = p(x, y; t)$ and $q = q(x, y; t)$ are the solutions to the linear base and auxiliary equations from Lemma 4 for which $g_0 = \hat{g}_0$ and $g(x, y; 0) = \delta(x - y)$. Let $\text{Dom}(d)$ denote the domain of the operator $d = -i \hbar \hat{c}_1$ where $\hbar = h(\hat{c}_1)$ is defined above. Then there exists a $T > 0$ such that the solution $g \in C^\infty([0, T]; \text{Dom}(d) \cap L^2(\mathbb{R}^2; \mathbb{C}))$ to the linear Fredholm equation

$$
p(x, y; t) = \int_\mathbb{R} g(x, z; t) q(z, y; t) \, dz.
$$

solves the evolutionary partial differential equation with odd degree nonlocal nonlinearity of the form

$$
\hat{c}_1 g = -i \hbar \hat{c}_1 g - g \ast f^*(g \ast g^\dagger).
$$
Proof From Remark 9 we know that with a slight modification of Lemma 1 for some $T > 0$ there exists a solution $g \in C^\infty([0,T]; \text{Dom}(d) \cap L^2(\mathbb{R}^2; \mathbb{C}))$ to the linear Fredholm equation (Riccati relation) shown. The solution $g$ is the integral kernel of $G$, which solves the Odd Degree Evolution Equation in Theorem 2. Writing that equation in terms of the kernel function $g$ corresponds to the partial differential equation with odd degree nonlocal nonlinearity shown.

Remark 10 We make the following observations: (i) Though we have a closed form for $p = p(x, y; t)$ in this case, $q = q(x, y; t)$ has a series representation. However as for our results in §2, time $t$ plays the role of a parameter in the sense that we decide on the time at which we wish to evaluate the solution, and then we solve the Fredholm equation to generate the solution $g$ for that time $t$; (ii) Also as for our results in §2, on the interval of time for which we know $g$ exists, its regularity is determined by the regularity of $p$; and (iii) The extension of our results above to the case when $p, q$ and $g$ are $C^\infty$-valued functions for any $n \in \mathbb{N}$ is straightforward.

There are many generalizations and concomitant results we intend to pursue. A few immediate ones are as follows. In all cases we assume the base equation to be $\partial_t P = DP$ and the Riccati relation has the form $P = GQ$. First, in the nonlocal cubic case assume the auxiliary equation has the form $\partial_t Q = (PAP^\dagger)Q$ for some linear operator $A$ satisfying $A^\dagger = -A$. This generates the cubic form of the operator equation for $G$ in the Odd Degree Evolution Equation Theorem 2 above. However we observe $\partial_t (QAQ^\dagger) = [PAP^\dagger, QAQ^\dagger]$. Hence if the commutator on the right vanishes initially then $QAQ^\dagger$ maintains its initial value thereafter. If we assume $Q_0AQ_0^\dagger = i\alpha \cdot 1$ then we recover the same result as that in Theorem 2 with the scalar $\alpha$ forced to be real from the skew-Hermitian property of $A$. Second, suppose the auxiliary equation has the form $\partial_t Q = (A_1PA_2P^\dagger A_3)Q$ for some operators $A_1, A_2$ and $A_3$. Assuming $Q$ satisfies the constraint $QA_2Q^\dagger = K$ for some time independent operator $K$ then $G$ can be shown to satisfy $\partial_t G = DG - G(A_2GKA_3)$. However, if $A_2^\dagger = -A_2$ and $A_3 = \pm A_1^\dagger$, then we observe that $\partial_t (QAQ^\dagger) = \pm[A_1PA_2P^\dagger A_3, K]$. Hence similarly, if the commutator on the right vanishes initially and $Q_0A_2Q_0^\dagger = K$ initially, then this constraint is maintained thereafter. Third and lastly, we observe we could assume the auxiliary equation has the form $\partial_t Q = f(PP^\dagger)P$ to attempt to generate even degree equations. We address further generalizations in our Conclusion §5.

4 Examples

We consider six example evolutionary partial differential equations with nonlocal nonlinearities in detail. The first four examples are: (i) A reaction-diffusion system with nonlocal nonlinear reaction terms; (ii) The nonlocal Korteweg de Vries equation; (iii) A nonlocal nonlinear Schrödinger equation and (iv) A
fourth order nonlinear Schrödinger equation with a nonlocal sinusoidal nonlinearity. In each of these cases we provide the following. First, we present the evolutionary system and initial data and explain how it fits into the context of one of the systems presented in §2 or §3. Second, we briefly explain how we simulated the evolutionary system with nonlocal nonlinearity directly by adapting well-known algorithms, mainly pseudo-spectral, for the versions of these systems with local nonlinearities. We denote these directly computed solutions by \( g_D \). Third, we explain in some more detail how we generated solutions from the underlying linear base and auxiliary equations and the linear Riccati relation. We denote solutions computed using our Riccati method by \( g_R \). Then for a particular evaluation time \( T > 0 \) we compute \( g_D \) and \( g_R \). We compare the two simulation results and explicitly plot their difference at that time \( T \). We also quote a value for the maximum norm over the spatial domain of the difference \( g_D - g_R \). Additionally we plot the evolution of \( \text{det}_2(\mathbf{id} + Q'(t)) \), and in the first two examples \( \|Q'(t)\|_{L_2(Q;\mathcal{Q})} \). We emphasize that for all the examples, to compute \( g_R \) we simply evaluate the explicit forms for \( p = p(x, y; t) \) and \( q' = q'(x, y; t) \) or their Fourier transforms at the given time \( t = T \). We then solve the corresponding Fredholm equation at time \( t = T \) to generate \( g_R \). The evolution plots for \( \text{det}_2(\mathbf{id} + Q'(t)) \) and \( \|Q'(t)\|_{L_2(Q;\mathcal{Q})} \) are provided for interest and analysis only. We remark that in some examples, at the evaluation times \( t = T \), the norm \( \|Q'(t)\|_{L_2(Q;\mathcal{Q})} \) is greater than one. This suggests that the estimates in Lemma 1, whilst guaranteeing the behaviour required, are somewhat conservative. All the simulations are developed on the domain \([-L/2, L/2]^2\) with the problem projected spatially onto \( M^2 \) nodes, i.e. \( M \) nodes for the \( x \in [-L/2, L/2] \) interval and \( M \) nodes for the \( y \in [-L/2, L/2] \) interval. Naturally \( M^2 \) also represents the number of two-dimensional Fourier modes in our simulations. In each case we quote \( L \) and \( M \). All our Matlab codes are provided in the supplementary electronic material.

The last two examples we present represent interesting special cases of our Riccati approach. They are: (v) Scalar evolutionary diffusive partial differential equation with a convolutional nonlinearity and (vi) Nonlocal Fisher–Kolmogorov–Petrovskii–Piskunov equation from biology/ecological systems. In the latter case we derive solutions for general initial data constructed using our approach. As far as we know these have not been derived before.

**Example 1 (Reaction-diffusion system with nonlocal reaction terms)** In this case the target equation is the system of reaction-diffusion equations with nonlocal reaction terms of the form

\[
\begin{align*}
\partial_t u &= d_{11} u + d_{12} v - u \ast (b_{11} u) - u \ast (b_{12} v) - v \ast (b_{12} u) - v \ast (b_{11} v), \\
\partial_t v &= d_{11} v + d_{12} u - u \ast (b_{11} v) - u \ast (b_{12} u) - v \ast (b_{12} v) - v \ast (b_{11} u),
\end{align*}
\]

where \( u = u(x, y; t) \) and \( v = v(x, y; t) \). We assume \( d_{11} = c_1^2 + 1, d_{12} = -1/2, b_{12} = 0 \) and \( b_{11} = N(x, \sigma) \), the Gaussian probability density function with mean zero. We set \( \sigma = 0.1 \). We take the initial profiles \( u_0(x, y) := \text{sech}(x + y) \text{sech}(y) \) and \( v_0(x, y) := \text{sech}(x + y) \text{sech}(x) \), and in this case \( L = 20 \) and
Partial differential systems with nonlocal nonlinearities

$M = 2^7$. This system fits into our general theory in §2 when we take $p$, $q$ and $g$ to have the $2 \times 2$ bisymmetric forms

$$
p = \begin{pmatrix} p_{11} & p_{12} \\
p_{21} & p_{22} \end{pmatrix}, \quad q = \begin{pmatrix} q_{11} & q_{12} \\
q_{21} & q_{22} \end{pmatrix}, \quad g = \begin{pmatrix} g_{11} & g_{12} \\
g_{21} & g_{22} \end{pmatrix}.
$$

We also assume similar forms for $d$ and $b$ with the components indicated above. Note that the product of two $2 \times 2$ bisymmetric matrices is bisymmetric. The resulting evolutionary Riccati equation $\dot{h}_1 G = dG - G(bG)$ in terms of the kernel functions $g_{11} = u$ and $g_{12} = v$ is the target reaction-diffusion system with nonlocal nonlinearities above. The results of our simulations are shown in Figure 1.

The top two panels show the $u$ and $v$ components of the solution computed up until time $T = 0.5$ using a direct spectral integration approach. By this we mean we solved the system of equations in Fourier space for $\hat{u} = \hat{u}(k, \kappa; t)$ and $\hat{v} = \hat{v}(k, \kappa; t)$. We used the Matlab built-in integrator ode45 to integrate in time. The middle two panels show the $g_{11}$ and $g_{12}$ components of the solution computed using our Riccati approach which respectively correspond to $u$ and $v$. To generate the solutions $g_{11}$ and $g_{12}$ we solved the $2 \times 2$ matrix Fredholm equation for $g$ computing $p$ and $q$ as $2 \times 2$ matrices directly from their explicit Fourier transforms. We approximated the integral in the Fredholm equation using a simple Riemann rule and used the built-in Matlab Gaussian elimination solver to find the solution. The bottom left panel shows the Euclidean norm of the difference $\|u - g_{11}, v - g_{12}\|$ for all $(x, y) \in [-L/2, L/2]^2$ at time $t = T$. The solutions numerically coincide and indeed for that time $t = T$ we have $\|u - g_{11}, v - g_{12}\|_{L^\infty([-L/2, L/2]^2)} = 3.6178 \times 10^{-5}$. We also computed the mean values of $|u - g_{11}|$ and $|v - g_{12}|$ over the domain which are, respectively, $8.7796 \times 10^{-8}$ and $1.6967 \times 10^{-7}$. The bottom right panel shows the evolution of $\det_G(\hat{G}(t))$ and also $|G(t)|_{[1, 2, 2]}$ for $t \in [0, T]$.

**Example 2 (Nonlocal Korteweg de Vries equation)** In this case the target equation is the nonlocal Korteweg de Vries equation

$$
\partial_t g = -\partial_x^3 g - g \ast (\partial_x g),
$$

for $g = g(x, y; t)$. Using our analysis in §2 we thus need to set $d = -\partial_x^3$ and $b = \partial_x$. We choose an initial profile of the form $\hat{g}_0(x, y) := \text{sech}^2(x + y) \text{sech}^2(y)$ and in this case $L = 40$ and $M = 2^8$. The results are shown in Figure 2. The top left panel shows the solution $g$ computed up until time $T = 1$ using a direct integration approach. By this we mean we implemented a split-step Fourier Spectral approach modified to deal with the nonlocal nonlinearity; we adapted the code from that found at the Wikiwaves webpage [37]. With the initial matrix $\hat{g}_0 := \hat{g}_0$, indexed by the wavenumbers $k$ and $\kappa$, the method is given by (here $\mathcal{F}$ denotes the Fourier transform),

$$
\hat{\sigma}_n := \exp(\Delta t K^3) \hat{\sigma}_n \quad \text{and} \quad \hat{\sigma}_{n+1} := \hat{\sigma}_n + \Delta t h \mathcal{F}\left( (\mathcal{F}^{-1}(\hat{\sigma}_n)) (\mathcal{F}^{-1}(K\hat{\sigma}_n)) \right),
$$

where $K$ is the diagonal matrix of Fourier coefficients $2\pi ik$ and where the product between the two inverse Fourier transforms shown is the matrix product.
Fig. 1 We plot the solution to the nonlocal reaction-diffusion system from Example 1. We used generic initial profiles $u_0(x, y) := \text{sech}(x + y) \text{sech}(y)$ and $v_0(x, y) := \text{sech}(x + y) \text{sech}(x)$. For time $T = 0.5$, the top panels show the $u$ and $v$ components of the solution computed using a direct integration approach while the middle panels show the corresponding $g_{11}$ and $g_{12}$ components of the solution computed using our Riccati approach. The bottom left panel shows the Euclidean norm of the difference $(u - g_{11}, v - g_{12})$ for all $(x, y) \in [-L/2, L/2]^2$. The bottom right panel shows the evolution of the Fredholm Determinant and Hilbert–Schmidt norm associated with $Q^t(t)$ for $t \in [0, T]$. 
In practice of course we used the fast Fourier transform. Note we have chosen to approximate the nonlocal nonlinear term using a Riemann rule. Further we used the time step $\Delta t = 0.0001$. The top right panel shows the solution $g_R$ computed using our Riccati approach. By this we mean the following. We computed the explicit solutions for the base and auxiliary equations in this case in Fourier space in the form

$$\hat{p}(k, \kappa; t) = e^{i(2\pi ik)^3} \hat{g}_0(k, \kappa),$$

and

$$\hat{q}'(k, \kappa; t) = \frac{(2\pi i k)^3 - 1}{(2\pi i k)^3} \hat{g}_0(k, \kappa).$$

Recall $q'$ is the kernel associated with $Q' = Q - 1d$. After computing the inverse Fourier transforms of these expressions we then solved the Fredholm equation, i.e. the Riccati relation, for $\hat{g} = \hat{g}(x, y; t)$ numerically. There are three sources of error in this computation. The first is the wavenumber cut-off and inverse fast Fourier transform required to compute $p$ of error in this computation. The first is in the choice of integral approximation in the Fredholm equation in the form

$$\Delta t$$

we used the time step $\Delta t$ to approximate the nonlocal nonlinear term using a Riemann rule. Further in practice of course we used the fast Fourier transform. Note we have chosen

$$\hat{p}(k, \kappa; t) = e^{i(2\pi ik)^3} \hat{g}_0(k, \kappa),$$

and

$$\hat{q}'(k, \kappa; t) = \frac{(2\pi i k)^3 - 1}{(2\pi i k)^3} \hat{g}_0(k, \kappa).$$

Recall $q'$ is the kernel associated with $Q' = Q - 1d$. After computing the inverse Fourier transforms of these expressions we then solved the Fredholm equation, i.e. the Riccati relation, for $\hat{g} = \hat{g}(x, y; t)$ numerically. There are three sources of error in this computation. The first is the wavenumber cut-off and inverse fast Fourier transform required to compute $p = p(x, y; t)$ and $q' = q'(x, y; t)$ respectively from $\hat{p}$ and $\hat{q}'$ above. The second is in the choice of integral approximation in the Fredholm equation. We used a simple Riemann rule. The third is the error in solving the corresponding matrix equation representing the Fredholm equation which is that corresponding to the error for Matlab’s inbuilt Gaussian elimination solver. The bottom left panel shows the absolute value of $g_D - g_R$. Up to computation error, the solutions naturally coincide, and indeed $\|g_D - g_R\|_{L^\infty([x, y]; \mathbb{R})} \approx 8.871 \times 10^{-5}$. The bottom right panel shows the evolution of $\text{det}_x(1d + Q(t))$ and also $\|Q(t)\|_{L^2([x, y]; \mathbb{R})}$ for $t \in [0, T]$.

Example 3 (Nonlocal nonlinear Schrödinger equation) In this case the target equation is the nonlocal nonlinear Schrödinger equation

$$i\partial_t g = \partial_x^2 g + g \ast g \ast g,$$

for $g = g(x, y; t)$. In our analysis in §3 we thus need to set $h(x) = x^2$ and $f(x) = x$. Further for computations we take the initial profile to be $g_0(x, y) := \text{sech}(x + y) \text{sech}(y)$ and in this case $L = 20$ and $M = 2^8$. The results are shown in Figure 3. The top two panels show the real and imaginary parts of the solution $g_0$ computed up until time $T = 0.02$ using a direct integration approach. By this we mean we implemented a split-step Fourier transform approach slightly modified to deal with the nonlocal nonlinearity; see Dutykh, Chhay and Fedele [13, p. 225]. The middle two panels show the real and imaginary parts of the solution $g_R$ computed using our Riccati approach. By this we mean, given the explicit solution for $\hat{p} = \hat{p}(k, \kappa; t)$ in terms of $\hat{g}_0$, we numerically evaluated $\hat{g} = \hat{g}(k, \kappa; t)$ using the exponential form from Lemma 4. In practice this consists of computing a large matrix exponential, our first source of error. We then solved the the Riccati relation in Fourier space when it takes the form $\hat{p}(k, \kappa; t) = \int \hat{g}(k, \nu; t) \hat{q}(\nu, \kappa; t) \, d\nu$ for $\hat{g} = \hat{g}(k, \kappa; t)$. We solved this Fredholm equation numerically and recovered $g = g(x, y; t)$ as the inverse Fourier transform of $\hat{g} = \hat{g}(k, \kappa; t)$. There are three further sources of error in this computation. The first is in the choice of integral approximation on the right-hand side. We used a simple Riemann rule. The second
Fig. 2 We plot the solution to the nonlocal Korteweg de Vries equation from Example 2. We used the generic initial profile $g_0(x, y) := \text{sech}^2(x+y)\text{sech}^2(y)$. For time $T = 1$, the top panels show the solution computed using a direct integration approach (left) and the corresponding solution computed using our Riccati approach (right). The bottom left panel shows the absolute value of the difference of the two computed solutions. The bottom right panel shows the evolution of the Fredholm Determinant and Hilbert–Schmidt norm associated with $Q'(t)$ for $t \in [0, T]$.

is the error in solving the corresponding matrix equation representing the Fredholm equation which is that corresponding to the error for Matlab’s in build Gaussian elimination solver. The third is in computing the inverse fast Fourier transform for the solution. The bottom left panel shows $|g_D - g_R|$ for all $(x, y) \in [-L/2, L/2]^2$ at time $t = T$. Up to computation error, the solutions coincide, and we have $\|g_D - g_R\|_{L^\infty(\mathbb{R}^2; \mathbb{C})} = 2.6932 \times 10^{-5}$. The bottom right panel shows the evolution of $\det_2(\mathcal{Q}(t))$ for $t \in [0, T]$, i.e. the Fredholm determinant of the Fourier transform $\hat{g}$ of the kernel $q$ associated with $Q$. Not too surprisingly we observe $|\det_2(\mathcal{Q}(t))| = 1$ for all $t \in [0, T]$.

Example 4 (Fourth order NLS with nonlocal sinusoidal nonlinearity) In this case the target equation is the fourth order nonlocal nonlinear Schrödinger equation

$$i\partial_t g = \partial_4^4 g + g \ast \sin^*(g \ast g'),$$
Fig. 3 We plot the solution to the cubic nonlocal nonlinear Schrödinger equation from Example 3. We used a generic initial profile $g_0(x, y) := \text{sech}(x+y) \text{sech}(y)$. For time $T = 0.02$, the top panels show the real and imaginary parts of the solution computed using a direct integration approach while the middle panels show the corresponding real and imaginary parts of the solution computed using our Riccati approach. The bottom left panel shows the magnitude of the difference between the two computed solutions. The bottom right panel shows the evolution of the Fourier transform of the Fredholm determinant associated with $Q(t)$ for $t \in [0, T]$ in the complex plane.
for $g = g(x, y; t)$. In our analysis in §3 we thus need to set $h(x) = x^4$ and $f(x) = \sin(x)$. The initial profile is $g_0(x, y) := \text{sech}(x + y) \text{sech}(y)$, as previously and in this case $L = 20$ and $M = 2^8$. The results are shown in Figure 4. The top two panels show the real and imaginary parts of the solution $g_D$ computed up until time $T = 0.2$ using a direct integration approach. By this we mean we implemented the split-step Fourier transform approach as in the last example, slightly modified to deal with the sinusoidal nonlinearity, and with time step $\Delta t = 0.0001$. The middle two panels show the real and imaginary parts of the solution $g_R$ computed using our Riccati approach. Again by this we mean, given the explicit solution for $\hat{p} = \hat{p}(k, \kappa; t)$ in terms of $\hat{g}_0$, we numerically evaluated $\hat{q} = \hat{q}(k, \kappa; t)$ and so forth, as described in the last example. The bottom left panel shows $|g_D - g_R|$ for all $(x, y) \in [-L/2, L/2]^2$ at time $t = T$. Thus again, up to computation error, the solutions naturally coincide with $\|g_D - g_R\|_{L^2(\mathbb{R}^2; C)} = 5.2793 \times 10^{-6}$. As in the last example, the bottom right panel shows the evolution of $|\det_2(\hat{Q}(t))|$ for $t \in [0, T]$. Again we observe that $|\det_2(\hat{Q}(t))| = 1$ for all $t \in [0, T]$.

We now present the two special case examples. The first is a very special case of the systems in §2 for which the subspace $Q$ has co-dimension one with respect to $H$. We can think of the operator $P$ being parameterized by an infinite row vector. The second is another special case when the Riccati relation represents a rank-one transformation from $Q$ to $P$. Here we use this context to solve a particular version of the nonlocal Fisher–Kolmogorov–Petrovskii–Piskunov equation. The Cole–Hopf transformation for the Burgers equation also represents such a rank-one case; see Beck et al. [5].

**Example 5** (Evolutionary diffusive PDE with convolutional nonlinearity) In this example we assume the linear base and auxiliary equations have the form

$$\partial_t p(y; t) = d(\partial_y) p(y; t) \quad \text{and} \quad \partial_t q(y; t) = b(\partial_y) p(y; t).$$

In these equations we assume the operator $d = d(\partial_y)$ is a polynomial in $\partial_y$ with constant coefficients and that it is of diffusive or dispersive type as described in §2. We also assume $b = b(\partial_y)$ is a polynomial in $\partial_y$ with constant coefficients.

We now posit the Riccati relation

$$p(y; t) = \int_{\mathbb{R}} g(z; t) q(z + y; t) \, dz.$$

Following Remark 5 in §2 by differentiating this Riccati relation with respect to time and using that $p = p(y; t)$ and $q = q(y; t)$ satisfy the scalar linear base
We plot the solution to the nonlocal nonlinear Schrödinger equation with a sinusoidal nonlinearity from Example 4. We used a generic initial profile $g_0(x, y) = \text{sech}(x) \text{sech}(y)$.

For time $T = 0.2$, the top panels show the real and imaginary parts of the solution computed using a direct integration approach while the middle panels show the corresponding real and imaginary parts of the solution computed using our Riccati approach. The bottom left panel shows the magnitude of the difference between the two computed solutions. The bottom right panel shows the evolution of the Fourier transform of the Fredholm determinant associated with $\tilde{Q}(t)$ for $t \in [0, T]$ in the complex plane.
and auxiliary equations above, we find
\[
\int_{\mathbb{R}} \partial_z g(z; t) q(z + y; t) \, dz = \partial_z p(y; t) - \int_{\mathbb{R}} g(z; t) \partial_z q(z + y; t) \, dz \\
= d(\partial_z) p(y; t) - \int_{\mathbb{R}} g(z; t) b(\partial_z) p(z + y; t) \, dz \\
= \int_{\mathbb{R}} g(z; t) d(\partial_z) q(z + y; t) \, dz \\
- \int_{\mathbb{R}} g(z; t) b(\partial_z) \int_{\mathbb{R}} g(\zeta; t) q(\zeta + z + y; t) \, d\zeta \, dz \\
= \int_{\mathbb{R}} (d(-\partial_z) g(z; t)) q(z + y; t) \, dz \\
- \int_{\mathbb{R}} (b(-\partial_z) g(z; t)) \int_{\mathbb{R}} g(\xi; t) q(\xi + z + y; t) \, d\xi \, dz \\
= \int_{\mathbb{R}} (d(-\partial_z) g(z; t)) q(z + y; t) \, dz \\
- \int_{\mathbb{R}} \int_{\mathbb{R}} (b(-\partial_z) g(\xi; t)) g(z - \xi; t) \, d\xi \, q(z + y; t) \, dz.
\]

Here we integrated by parts assuming suitable decay in the far-field, used the substitution \( \xi = \zeta + z \) for fixed \( z \), and swapped over the integration variables \( \xi \) and \( z \). As in Remark 5, if we postmultiply by \( \delta(z - y) + \tilde{q}(y, \eta; t) \) and integrate over \( y \in \mathbb{R} \) we find \( g = g(\eta; t) \) satisfies
\[
\partial_z g(\eta; t) = d(-\partial_z) g(\eta; t) - \int_{\mathbb{R}} (b(-\partial_z) g(\xi; t)) g(\eta - \xi; t) \, d\xi.
\]

This is a simpler derivation of Example 1 from Beck et al. [5] where \( b = 1 \).

There we derive an explicit form for the Fourier transform of the solution and compare the result of direct numerical simulations with evaluation of the solution using our explicit formula.

**Example 6 (Nonlocal Fisher–Kolmogorov–Petrovskii–Piskunov equation)** In this example we assume the scalar linear base and auxiliary equations have the form
\[
\partial_t p(x; t) = d(\partial_x) p(x; t) \quad \text{and} \quad \partial_t q(x; t) = b(x, \partial_x) p(x; t).
\]

Here the operator \( d = d(\partial_x) \) is assumed to be a polynomial in \( \partial_x \) with constant coefficients of diffusive or dispersive type as described in §2. We assume that the operator \( b = b(x, \partial_x) \) is either of the form \( b = b(x) \) only, where \( b(x) \) is a bounded function, or it is of the form \( b = b(\partial_x) \) only, in which case we assume it is a polynomial in \( \partial_x \) with constant coefficients. We could assume \( b = b(x, \partial_x) \) too. Then, the solution can be written as
\[
\hat{\partial}_t \hat{g}(\eta; t) = \hat{d}(\partial_x) \hat{g}(\eta; t) - \int_{\mathbb{R}} (\hat{b}(-\partial_x) \hat{g}(\xi; t)) \hat{g}(\eta - \xi; t) \, d\xi.
\]
is a polynomial in $\hat{e}_x$ with non-homogeneous coefficients, the main constraint is whether we can find an explicit form for the solution $q = q(x; t)$ to the linear auxiliary equation. We now posit the Riccati relation of the following rank-one form

$$p(x; t) = g(x; t) \int q(z; t) \, dz.$$  

For convenience we set $\bar{\eta}(t) := \int q(z; t) \, dz$, in which case we have $p(x; t) = g(x; t) \bar{\eta}(t)$ and

$$\hat{e}_t \bar{\eta}(t) = \int b(z, \hat{e}_z) p(z; t) \, dz.$$  

As in §2, in particular for example in Remark 5, we differentiate the Riccati relation with respect to time and substitute in that $p = p(x; t)$ satisfies the linear base equation and $\bar{\eta} = \bar{\eta}(t)$ satisfies the equation just above. Carrying this through generates

$$\left( \hat{e}_t g(x; t) \right) \bar{\eta}(t) = \hat{e}_t p(x; t) - g(x; t) \hat{e}_t \bar{\eta}(t)$$  

$$= d(\hat{e}_x)p(x; t) - g(x; t) \int b(z, \hat{e}_z) p(z; t) \, dz$$  

$$= d(\hat{e}_x)g(x; t) \bar{\eta}(t) - g(x; t) \int b(z, \hat{e}_z) g(z; t) \, dz \bar{\eta}(t).$$  

Dividing through by $\bar{\eta} = \bar{\eta}(t)$ generates the equation

$$\hat{e}_t g(x; t) = d(\hat{e}_x)g(x; t) - g(x; t) \int b(z, \hat{e}_z) g(z; t) \, dz.$$  

Now suppose we wish to solve this evolutionary partial differential equation with the nonlocal nonlinearity shown for some given initial data $g_0(x)$, i.e. such that $g(x; 0) = g_0(x)$. We naturally take $\bar{\eta}(0) = 1$ and $p(x; 0) = g_0(x)$. Then that $g(x; t) = p(x; t) \bar{\eta}(t)$ is indeed the corresponding solution to the evolutionary partial differential equation for $g = g(x; t)$ above, with $p = p(x; t)$ satisfying the linear base equation above and $\bar{\eta} = \bar{\eta}(t)$ satisfying the integrated auxiliary equation shown, can be verified by direct substitution.

Let us now consider the special case $b = 1$. Then by analogy with Lemma 2, the solution $p = p(x; t)$ to the linear base equation is given in terms of its Fourier transform by

$$\hat{p}(k; t) = \exp\left(d(2\pi ik) t \right) \hat{g}_0(k).$$  

By taking the inverse Fourier transform of this and integrating with respect to the spatial coordinate, we find the solution $\bar{\eta} = \bar{\eta}(t)$ to the integrated auxiliary equation is then given by

$$\bar{\eta}(t) = 1 + \left( \frac{\exp(t \, d(0)) - 1}{d(0)} \right) \hat{g}_0(0).$$  

If $d(0) = 0$, this becomes $\bar{\eta}(t) = 1 + t \hat{g}_0(0)$. Hence we have an explicit solution for any diffusive or dispersive form for $d = d(\hat{e}_x)$. If $d(\hat{e}_x) = \hat{e}_x^2 + 1$, the partial differential equation for $g = g(x; t)$ above corresponds to a particular version of the nonlocal Fisher–Kolmogorov–Petrovskii–Piskunov equation which is studied for example in Britton [9] and Bian, Chen & Latos [7].
5 Conclusion

We have extended our Riccati approach for generating solutions to nonlocal nonlinear partial differential equations from a corresponding linear base equation to systems as well as higher odd degree nonlinearities. These systems can be of arbitrary order in the linear terms and include higher order terms in the nonlocal nonlinear terms. We also provided explicit calculations demonstrating how solutions for such nonlocal nonlinear systems can be generated in this manner for general initial data. For four example systems we also provided numerical simulations comparing solutions computed using the Riccati approach and solutions computed using direct primarily pseudo-spectral numerical methods. We provide all the Matlab codes in the supplementary electronic material. We also indicated multiple immediate extensions we intend to consider, for example to tackle the case of higher even degree nonlinearities. Additionally we hinted on how we intend to extend the Riccati approach to the multi-dimensional nonlocal nonlinear partial differential equations.

There are many further extensions and practical considerations in our sights. One natural extension is to consider using the Riccati approach for nonlocal nonlinear stochastic partial differential equations. We would begin with those with additive space-time noise which could be incorporated via the operator $C$ in the quadratic nonlocal nonlinearity set-up described in §2. It appears as a linear term in the base equation which would thus become a linear stochastic partial differential equation. The base and auxiliary equations would have to be solved as a linear system, which is achievable in principle. Then the term $C$ appears as a nonhomogeneous source term in the final Riccati stochastic partial differential equation. Indeed we have already performed some simulations of this nature and these will be published in Doikou, Malham and Wiese [11]. On the practical consideration side, we note that to compute solutions using the Riccati method in practice, we may need to approximate the solution to the linear auxiliary equation, and then typically, we need to solve the linear Fredholm integral equation numerically to find the desired solution. It would be useful to provide a comprehensive numerical analysis study examining the relative complexity of the Riccati approach in these cases compared to the state-of-the-art numerical methods available for such nonlinear systems.

The context and examples we have considered thus far have included large classes of nonlocal nonlinear systems. One way to classify these systems is that they can all be thought of as "big matrix" equations with the natural extended product encoded in the ‘•’ product. In other words we think of the linear operators $P, Q$ and $G$ as matrix operators extended to the infinite-dimensional context, whether countable or not. The resulting objects are either countably infinite matrices or are parametrized by integral kernels. The natural extension of the matrix product is then the countable discrete version of the star product or the star product itself. One of our next goals is to consider how to generalize our Riccati approach so as to incorporate local nonlinearities.
One natural approach is to replace the Fredholm Riccati relation by a Volterra one.

Lastly, the classes of nonlinear partial differential equations we have considered may have solutions which become singular in finite time. For example the nonlocal nonlinear Schrödinger equation with higher degree nonlinearity or in higher dimensions might exhibit such behaviour. However let us consider the overarching context of the Riccati approach we prescribe which is that of a linear subspace flow projected down onto the Fredholm Grassmannian. In principle the solutions to the underlying linear base and auxiliary equations which generate the solution to the nonlocal nonlinear system do not themselves become singular in finite time. The singularity in the nonlocal nonlinear system is just an artifact of a poor choice of coordinate patch on the Fredholm Grassmannian. It corresponds to the event \( \det_2 \left( \text{id} + Q'(t) \right) \to 0 \), though we need to be wary of a hierarchy of regularized determinants here that should be monitored. The coordinate patch choice is made in the projection

\[
\begin{pmatrix} Q \\ P \end{pmatrix} \to \begin{pmatrix} \text{id} \\ G \end{pmatrix}.
\]

Implicit in the projection as shown is that we have equivalenced by the “top” block of suitable general linear transformations, thus generating the graph and coordinate patch on the right shown. However we can equivalence by any block of suitable general linear transformations (for example the lower block instead) generating a different graph and coordinate patch. Indeed there is a Schubert cell decomposition of the Fredholm Grassmannian analogous to that in the finite-dimensional case; see Pressley and Segal [29]. Careful analysis of the behaviour of the solutions to the underlying linear base and auxiliary equations on the approach to and transcending through and beyond the singularity in a given coordinate patch might reveal more detailed information about the singularity and will provide a mechanism for continuing solutions beyond it.
