438 **Abstract**

439 High blood pressure is a highly heritable and modifiable risk factor for cardiovascular
440 disease. We report the largest genetic association study of blood pressure traits (systolic,
441 diastolic, pulse pressure) to date in over one million people of European ancestry. We
442 identify 535 novel blood pressure loci that not only offer new biological insights into blood
443 pressure regulation but also reveal shared genetic architecture between blood pressure and
444 lifestyle exposures. Our findings identify new biological pathways for blood pressure
445 regulation with potential for improved cardiovascular disease prevention in the future.

446

447 INTRODUCTION

448 High blood pressure (BP) is a leading heritable risk factor for stroke and coronary artery
449 disease, responsible for an estimated 7.8 million deaths and 148 million disability life years
450 lost worldwide in 2015 alone¹. Blood pressure is determined by complex interactions
451 between life-course exposures and genetic background²⁻⁴. Previous genetic association
452 studies have identified and validated variants at 274 loci with modest effects on population
453 BP, explaining in aggregate ~3% of the trait variance⁵⁻¹².

454 Here, we report genome-wide discovery analyses of BP traits - systolic (SBP), diastolic (DBP)
455 and pulse pressure (PP) - in people of European ancestry drawn from UK Biobank (UKB)¹³
456 and the International Consortium of Blood Pressure-Genome Wide Association Studies
457 (ICBP)^{11,12}. We adopted a combination of a one- and two-stage study design to test common
458 and low-frequency single nucleotide polymorphisms (SNPs) with minor allele frequency
459 (MAF) $\geq 1\%$ associated with BP traits (**Fig. 1**). In all, we studied over 1 million people of
460 European descent, including replication data from the US Million Veterans Program (MVP,
461 N=220,520)¹⁴ and the Estonian Genome Centre, University of Tartu (EGCUT, N=28,742)
462 Biobank¹⁵.

463 UKB is a prospective cohort study of ~500,000 richly phenotyped individuals, including BP
464 measurements¹³, with genotyping by customized array and imputation from the Haplotype
465 Reference Consortium (HRC) panel, yielding ~7 million SNPs (imputation quality score (INFO)
466 ≥ 0.1 and MAF $\geq 1\%$)¹⁶. We performed genome-wide association studies (GWAS) of BP traits
467 (N=458,577 Europeans) under an additive genetic model¹⁷ (**Supplementary Table 1a**).
468 Following LD-score regression¹⁸, genomic control (GC) was applied to the UKB data prior to
469 meta-analysis (Online methods).

470 In addition, we performed GWAS analyses for BP traits in newly extended ICBP GWAS data
471 comprising 77 independent studies for up to 299,024 Europeans genotyped with various
472 arrays, and imputed to either the 1,000 Genomes Reference Panel or the HRC platforms
473 (**Supplementary Table 1b**). After QC we applied GC at the individual study level and
474 obtained summary effect sizes for ~7 million SNPs with INFO ≥ 0.3 and heterogeneity
475 Cochran's Q statistic¹⁹ filtered at $P \geq 1 \times 10^{-4}$ (Online Methods).

476 We then combined the UKB and ICBP GWAS results using inverse-variance weighted fixed
477 effects meta-analysis (Online Methods), giving a total discovery sample of up to 757,601
478 individuals²⁰.

479 In our two-stage design we attempted replication (in MVP and EGCUT, **Supplementary**
480 **Table 1c**) of 1,062 SNPs at $P < 1 \times 10^{-6}$ from discovery with concordant effect direction
481 between UKB and ICBP, using the sentinel SNP (i.e. SNP with smallest P -value at the locus)
482 after excluding the HLA region (chr 6:25-34MB) and all SNPs in Linkage Disequilibrium (LD)
483 ($r^2 \geq 0.1$) or ± 500 Kb from any previously validated BP-associated SNPs at the 274 published
484 loci. Our replication criteria were genome-wide significance ($P < 5 \times 10^{-8}$) in the combined
485 meta-analysis, $P < 0.01$ in the replication data and concordant direction of effect between
486 discovery and replication.

487 We additionally undertook a one-stage design to reduce type II error from the two-stage
488 analysis. We used $P < 5 \times 10^{-9}$ as threshold from the discovery meta-analysis, i.e. an order of
489 magnitude more stringent than genome-wide significance²¹, and required an internal
490 replication $P < 0.01$ in each of the UKB and ICBP GWAS analyses, with concordant direction
491 of effect, to minimize false positive findings.

492 We carried out conditional analyses using genome-wide complex trait analysis (GCTA)²². We
493 then explored putative function of BP-associated signals using a range of *in silico* resources,
494 and evaluated co-occurrence of BP-associated loci with lifestyle exposures and other
495 complex traits and diseases. Finally, we developed a genetic risk score (GRS) and assessed
496 impact of BP-associated variants on BP level, risk of hypertension (HTN), other
497 cardiovascular diseases and in other ethnicities.

498 RESULTS

499 We present a total of 535 novel loci (**Fig.2, Supplementary Fig. 1**): 325 loci claimed from the
500 two-stage design (**Supplementary Tables 2a-c**) and an additional 210 claimed from our one-
501 stage design with internal replication (**Supplementary Tables 3a-c**). Our two-stage design
502 uniquely identified 121 variants, while 204 also met the one-stage criteria (**Fig. 3a**); large
503 numbers of loci would not have been detected by either the one- or two-stage designs
504 alone (**Fig. 3a**). For SBP, the distributions of effect sizes are similar for the one-stage
505 (median = 0.219 mmHg per allele; Inter-Quartile Range (IQR) = 0.202-0.278) and two-stage
506 loci (median = 0.224; IQR = 0.195-0.267) ($P = 0.447$) (**Supplementary Fig. 2**). Of the 210 loci
507 found only in the one-stage analysis, 186 are also genome-wide significant ($P < 5 \times 10^{-8}$) in
508 the combined meta-analysis, with all variants, except one, having concordant direction of
509 effect between discovery and replication (**Supplementary Tables 3a-c**); of the remaining 24
510 SNPs, 10 still have concordant direction of effect.

511 We find support in our data for all 274 previously published BP loci (**Supplementary Fig. 1 &**
512 **2 and Supplementary Table 4**); >95% of the previously reported SNPs covered within our
513 data are genome-wide significant. Only 6 available SNPs did not reach Bonferroni-
514 significance, likely because they were originally identified in non-European ancestries (e.g.
515 rs6749447, rs10474346, rs11564022), or from a gene-age interaction analysis (rs16833934).
516 In addition, we confirmed a further 92 previously reported, but not replicated, loci
517 (**Supplementary Table 5**)⁹; together with 274 previously reported loci confirmed, and 535
518 novel loci identified here, there are 901 BP-associated loci in total.

519 Novel genetic loci for blood pressure

520 Of the 535 independent novel loci, 363 SNPs were associated with one trait, 160 with two
521 traits and 12 with all three BP traits (**Fig. 3b, Supplementary Fig. 3**). Using GCTA we
522 additionally identified 163, genome-wide significant, independent secondary signals with
523 MAF $\geq 1\%$ associated with BP (**Supplementary Table 6**), of which 19 SNPs are in LD ($r^2 \geq 0.1$)
524 with previously reported secondary signals. This gives a total of 144 new secondary signals;
525 hence we now report over 1,000 independent BP signals.

526 The estimated SNP-wide heritability (h^2) of BP traits in our data was 0.213, 0.212 and 0.194
527 for SBP, DBP and PP respectively, with a gain in percentage of BP variance explained. For

528 example, for SBP, percentage variance explained increased from 2.8 % for the 274
529 previously published loci to 5.7% for SNPs identified at all 901 loci (**Supplementary Table 7**).

530 **Functional analyses**

531 Our functional analyses approach is summarised in **Supplementary Figure 4**. First, for each
532 of the 901 loci we annotated all SNPs (based on LD $r^2 \geq 0.8$) to the nearest gene within 5kb
533 of a SNP, identifying 1333 genes for novel loci and 1272 genes for known loci. Then we
534 investigated these loci for tissue enrichment, DNase hypersensitivity site enrichment and
535 pathway analyses. At 66 of the 535 novel loci we identified 97 non-synonymous SNPs,
536 including 8 predicted to be damaging (**Supplementary Table 8**).

537 We used chromatin interaction Hi-C data from endothelial cells (HUVEC)²³, neural
538 progenitor cells (NPC), mesenchymal stem cells (HVMSC) and tissue from the aorta (HAEC)
539 and adrenal gland²⁴ to identify distal associated genes. There were 498 novel loci that
540 contained a potential regulatory SNP and in 484 of these we identified long-range
541 interactions in at least one of the tissues or cell types. We found several potential long-
542 range target genes that do not overlap with the sentinel SNPs in the LD block. For example,
543 the *TGFB2* gene forms a 1.2Mb regulatory loop with SNPs in the *SLC30A10* locus, and the
544 *TGFBR1* promoter forms a 100kb loop with the *COL15A1* locus (**Supplementary Table 8**).

545 Our eQTL analysis identified 60 novel loci with eQTLs in arterial and 20 in adrenal tissue
546 (**Supplementary Table 9**), substantially increasing those identified in our previously
547 published GWAS on ~140K UKB individuals¹⁰. An example is SNP rs31120122 which defines
548 an aortic eQTL affecting expression of the *MED8* gene within the *SZT2* locus. In combination
549 with Hi-C interaction data in MSC, this supports a role for *MED8* in BP regulation, possibly
550 mediated through repression of smooth muscle cell differentiation. Hi-C interactions
551 provide supportive evidence for involvement of a further 36 arterial eGenes (genes whose
552 expression is affected by the eQTLs) that were distal to their eQTLs (e.g *PPHLN1*, *ERAP2*,
553 *FLRT2*, *ACVR2A*, *POU4F1*).

554 Using DeepSEA we found 198 SNPs in 121 novel loci with predicted effects on transcription
555 factor binding or on chromatin marks in tissues relevant for BP biology, such as vascular
556 tissue, smooth muscle and the kidney (**Supplementary Table 8**).

557 We used our genome-wide data at a false discovery rate (FDR) < 1% to robustly assess tissue
558 enrichment of BP loci using DEPICT and identified enrichment across 50 tissues and cells.
559 (**Supplementary Fig 5a; Supplementary Table 10a**). Enrichment was greatest for the
560 cardiovascular system especially blood vessels ($P = 1.5 \times 10^{-11}$) and the heart ($P = 2.7 \times 10^{-5}$).
561 Enrichment was high in adrenal tissue ($P = 3.7 \times 10^{-4}$) and, for the first time, we observed
562 high enrichment in adipose tissues ($P = 9.8 \times 10^{-9}$) corroborated by eQTL enrichment
563 analysis ($P < 0.05$) (**Supplementary Fig. 6; Supplementary Table 9**). Evaluation of enriched
564 mouse knockout phenotype terms also points to the importance of vascular morphology (P
565 $= 6 \times 10^{-15}$) and development ($P = 2.1 \times 10^{-18}$) in BP. With addition of our novel BP loci, we
566 identified new findings from both the gene ontology and protein-protein interaction
567 subnetwork enrichments, which highlight the TGF β ($P = 2.3 \times 10^{-13}$) and related SMAD
568 pathways ($P = 7 \times 10^{-15}$) (**Supplementary Table 10b, Supplementary Fig. 5b-d**).

569 We used FORGE²⁵ to investigate the regulatory regions for cell type specificity from DNase I
570 hypersensitivity sites, which showed strongest enrichment ($P < 0.001$) in the vasculature
571 and highly vascularised tissues, as reported in previous BP genetic studies¹⁰ (**Supplementary**
572 **Fig. 7**).

573 **Potential therapeutic targets**

574 Ingenuity pathway analysis and upstream regulator assessment showed enrichment of
575 canonical pathways implicated in cardiovascular disease including pathways targeted by
576 antihypertensive drugs (e.g. nitric oxide signalling) and also suggested some potential new
577 targets, such as relaxin signalling. Notably, upstream regulator analysis identified several BP
578 therapeutic targets such as angiotensinogen, calcium channels, progesterone, natriuretic
579 peptide receptor, angiotensin converting enzyme, angiotensin receptors and endothelin
580 receptors (**Supplementary Fig. 8**).

581 We developed a cumulative tally of functional evidence at each variant to assist in
582 variant/gene prioritisation at each locus and present a summary of the vascular expressed
583 genes contained within the 535 novel loci, including a review of their potential druggability
584 (**Supplementary Fig. 9**). The overlap between BP-associated genes and those associated
585 with antihypertensive drug targets further demonstrates new genetic support for known
586 drug mechanisms. For example, we report five novel BP associations with targets of five
587 antihypertensive drug classes (**Supplementary Table 11**), including the *PKD2L1*, *SLC12A2*,
588 *CACNA1C*, *CACNB4* and *CA7* loci - targeted by potassium-sparing diuretics (amiloride), loop
589 diuretics (bumetanide and furosemide), dihydropyridine, calcium channel blockers, non-
590 dihydropyridines and thiazide-like diuretics (chlortalidone) respectively. Notably in all but
591 the last case, functional variants in these genes are the best candidates in each locus.

592 **Concordance of BP variants and lifestyle exposures**

593 We examined association of sentinel SNPs at the 901 BP loci with BP-associated lifestyle
594 traits¹⁴ in UKB using either the Stanford Global Biobank Engine (N=327,302) or Gene ATLAS
595 (N=408,455). With corrected $P < 1 \times 10^{-6}$, we found genetic associations of BP variants with
596 daily fruit intake, urinary sodium and creatinine concentration, body mass index (BMI),
597 weight, waist circumference, and intakes of water, caffeine and tea ($P = 1.0 \times 10^{-7}$ to $P = 1.3$
598 $\times 10^{-46}$). Specifically, SNP rs13107325 in *SLC39A8* is a novel locus for frequency of drinking
599 alcohol ($P = 3.5 \times 10^{-15}$) and time spent watching TV ($P = 2.3 \times 10^{-11}$) as well as being
600 associated with BMI ($P = 1.6 \times 10^{-33}$), weight ($P = 8.8 \times 10^{-16}$) and waist circumference ($P =$
601 4.7×10^{-11}) (**Supplementary Table 12**). We used unsupervised hierarchical clustering for the
602 36 BP loci that showed at least one association at $P < 1 \times 10^{-6}$ with the lifestyle-related traits
603 in UKB (**Fig. 4**). The heatmap summarises the locus-specific associations across traits and
604 highlights heterogeneous effects with anthropometric traits across the loci examined. For
605 example, it shows clusters of associations between BP-raising alleles and either increased or
606 decreased adult height and weight. We note that some observed cross-trait associations are
607 in counter-directions to those expected epidemiologically.

608 **Association lookups with other traits and diseases**

609 We further evaluated cross-trait and disease associations using GWAS catalog²⁶,
610 PhenoScanner²⁷ and DisGeNET^{28,29}. The GWAS catalog and PhenoScanner search of
611 published GWAS showed that 77 of our 535 novel loci (using sentinel SNPs or proxies; $r^2 \geq$
612 0.8) are also significantly associated with other traits and diseases (**Fig. 5, Supplementary**
613 **Table 13**). We identified *APOE* as a highly cross-related BP locus showing associations with
614 lipid levels, cardiovascular-related outcomes and Alzheimer's disease, highlighting a
615 common link between cardiovascular risk and cognitive decline (**Fig. 5**). Other loci overlap
616 with anthropometric traits, including BMI, birth weight and height (**Fig. 5**) and with
617 DisGeNET terms related to lipid measurements, cardiovascular outcomes and obesity (**Fig.**
618 **6**).

619 We did lookups of our sentinel SNPs in ¹H NMR lipidomics data on plasma (N=2,022) and
620 data from the Metabolon platform (N=1,941) in the Airwave Study³⁰, and used
621 PhenoScanner to test SNPs against published significant ($P < 5 \times 10^{-8}$) genome vs
622 metabolome-wide associations in plasma and urine (Online Methods). Ten BP SNPs show
623 association with lipid particle metabolites and a further 31 SNPs (8 also on PhenoScanner)
624 show association with metabolites on the Metabolon platform, highlighting lipid pathways,
625 amino acids (glycine, serine, glutamine), tri-carboxylic acid cycle intermediates
626 (succinylcarnitine) and drug metabolites (**Supplementary Tables 14 and 15**). These findings
627 suggest a close metabolic coupling of BP regulation with lipid and energy metabolism.

628 **Genetic risk of increased blood pressure, hypertension and cardiovascular disease**

629 A weighted GRS for BP levels across all 901 loci was associated with a 10.4 mmHg higher,
630 sex-adjusted mean SBP in UK Biobank comparing the upper and lower quintiles of the GRS
631 distribution (95% CI: 10.2 to 10.6 mm Hg, $P < 1 \times 10^{-300}$) and with 12.9 mmHg difference in
632 SBP (95% CI: 12.6 to 13.1, $P < 1 \times 10^{-300}$) comparing the upper and lower deciles (**Fig. 7a,**
633 **Supplementary Table 16**). In addition, we observed over three-fold sex-adjusted higher risk
634 of hypertension (OR 3.34; 95% CI: 3.24 to 3.45; $P < 1 \times 10^{-300}$) between the upper and lower
635 deciles of the GRS in UK Biobank (**Fig. 7a**). Sensitivity analyses in the independent Airwave
636 cohort gave similar results (**Supplementary Table 17**).

637 We also show that the GRS is associated with increased, sex-adjusted risk of incident stroke,
638 myocardial infarction and all incident cardiovascular outcomes, comparing upper and lower
639 deciles of the GRS distribution, with odds ratios of 1.47 (95% CI: 1.35 to 1.59, $P = 1.1 \times 10^{-20}$),
640 1.50 (95% CI: 1.28 to 1.76, $P = 8.0 \times 10^{-7}$) and 1.52 (95% CI: 1.26 to 1.82, $P = 7.7 \times 10^{-6}$)
641 respectively (**Fig. 7b, Supplementary Table 16**).

642 **Extending analyses to other ancestries**

643 We examined associations with BP of both individual SNPs and the GRS among unrelated
644 individuals of African and South Asian descent in UKB, for the 901 known and novel loci.
645 Compared to Europeans, 62.4%, 62.5% and 64.8% of the variants among Africans (N=7,782),
646 and 74.2%, 72.3% and 75% South Asians (N=10,323) have concordant direction of effect for
647 SBP, DBP and PP respectively (**Supplementary Table 18; Supplementary Fig. 10**). Pearson
648 correlation coefficients with effect estimates in Europeans were $r^2 = 0.37$ and 0.78 for
649 Africans and South Asians respectively (**Supplementary Fig. 11**). We then applied the

650 European-derived GRS findings to unrelated Africans (N=6,970) and South Asians (N=8,827).
651 BP variants in combination were associated with 6.1 mmHg (95% CI: 4.5 to 7.7; $P = 4.9 \times 10^{-14}$)
652 and 7.4 mmHg (95% CI: 6.0 to 8.7; $P = 1.7 \times 10^{-26}$) higher, sex-adjusted mean systolic
653 pressure among Africans and South Asians, respectively, comparing upper and lower
654 quintiles of the GRS distribution (**Supplementary Tables 19a and 19b**).

655 DISCUSSION

656 Our study of over 1 million people offers an important step forward in understanding the
657 genetic architecture of BP. We identified over 1,000 independent signals at 901 loci for BP
658 traits, and the 535 novel loci more than triples the number of BP loci and doubles the
659 percentage variance explained, illustrating the benefits of large-scale biobanks. By
660 explaining 27% of the estimated heritability for BP, we make major inroads into the missing
661 heritability influencing BP level in the population³¹. The novel loci open the vista of entirely
662 new biology and highlight gene regions in systems not previously implicated in BP
663 regulation. This is particularly timely as global prevalence of people with SBP over 110-115
664 mm Hg, above which cardiovascular risk increases in a continuous graded manner, now
665 exceeds 3.5 billion, of whom over 1 billion are within the treatment range^{32,33}.

666 Our functional analysis highlights the role of the vasculature and associated pathways in the
667 genetics underpinning BP traits. We show a role for several loci in the transforming growth
668 factor beta (TGF β) pathway including SMAD family genes and the *TGF β* gene locus itself.
669 This pathway affects sodium handling in the kidney, ventricular remodelling, while plasma
670 levels of TGF β have recently been correlated with hypertension (**Fig. 8**)^{34,35}. The activin A
671 receptor type 1C (*ACVR1C*) gene mediates the effects of the TGF β family of signalling
672 molecules. A BP locus contains the Bone Morphogenetic Protein 2 (*BMP2*) gene in the TGF β
673 pathway, which prevents growth suppression in pulmonary arterial smooth muscle cells and
674 is associated with pulmonary hypertension³⁶. Another BP locus includes the Kruppel-like
675 family 14 (*KLF14*) gene of transcription factors, induced by low levels of TGF β receptor II
676 gene expression, and which has also been associated with type 2 diabetes,
677 hypercholesterolaemia and atherosclerosis³⁷.

678 Our analysis shows enrichment of BP gene expression in the adrenal tissue. Autonomous
679 aldosterone production by the adrenal glands is thought to be responsible for 5-10% of all
680 hypertension, rising to ~20% amongst people with resistant hypertension³⁸. Some of our
681 novel loci are linked functionally to aldosterone secretion^{39,40}. For example, the *CTNNA1*
682 locus encodes β -catenin, the central molecule in the canonical Wnt signalling system,
683 required for normal adrenocortical development^{41,42}. Somatic adrenal mutations of this
684 gene that prevent serine/threonine phosphorylation lead to hypertension through
685 generation of aldosterone-producing adenomas^{43,44}.

686 Our novel loci also include genes involved in vascular remodelling, such as vascular
687 endothelial growth factor A (*VEGFA*), the gene product of which induces proliferation,
688 migration of vascular endothelial cells and stimulates angiogenesis. Disruption of this gene
689 in mice resulted in abnormal embryonic blood vessel formation, while allelic variants of this
690 gene have been associated with microvascular complications of diabetes, atherosclerosis
691 and the antihypertensive response to enalapril⁴⁵. We previously reported a fibroblast

692 growth factor (*FGF5*) gene locus in association with BP¹⁰. Here, we additionally identify a
693 new BP locus encoding FGF9, which is linked to enhanced angiogenesis and vascular smooth
694 muscle cell differentiation by regulating *VEGFA* expression.

695 Several of our novel loci contain lipid-related genes consistent with the observed strong
696 associations among multiple cardio-metabolic traits. For example, the apolipoprotein E
697 gene (*APOE*) encodes the major apoprotein of the chylomicron. Recently, APOE serum levels
698 have been correlated with SBP in population-based studies and in murine knockout models;
699 disruption of this gene led to atherosclerosis and hypertension^{46,47}. A second novel BP locus
700 contains the low-density lipoprotein receptor-related protein 4 (*LRP4*) gene which may be a
701 target for APOE and is strongly expressed in the heart in mice and humans. In addition, we
702 identified a novel locus including the apolipoprotein L domain containing 1 gene (*APOLD1*)
703 that is highly expressed in the endothelium of developing tissues (particularly heart) during
704 angiogenesis.

705 Many of our novel BP loci encode proteins which may modulate vascular tone or signalling.
706 For example, the locus containing urotensin-2 receptor (*UTS2R*) gene encodes a class A
707 rhodopsin family G-protein coupled-receptor that upon activation by the neuropeptide
708 urotensin II, produces profound vasoconstriction. One novel locus for SBP contains the
709 relaxin gene, encoding a G-protein coupled receptor, with roles in vasorelaxation and
710 cardiac function; it signals by phosphatidylinositol 3-kinase (PI3K)^{48,49}, an enzyme which
711 inhibits vascular smooth muscle cell proliferation and neo-intimal formation⁵⁰. We identify
712 the *PI3K* gene here as a novel BP locus. We also identify the novel *RAMP2* locus which
713 encodes an adrenomedullin receptor⁵¹; we previously identified the adrenomedullin (*ADM*)
714 gene as a BP locus¹². Adrenomedullin is known to exert differential effects on BP in the brain
715 (vasopressor) and the vasculature (vasodilator). In addition, a locus containing Rho guanine
716 nucleotide exchange factor 25 (*ARHGEF25*) gene generates a factor that interacts with Rho
717 GTPases involved in contraction of vascular smooth muscle and regulation of responses to
718 angiotensin II⁵².

719 We evaluated the 901 BP loci for extant or potentially druggable targets. Loci encoding
720 *MARK3*, *PDGFC*, *TRHR*, *ADORA1*, *GABRA2*, *VEGFA* and *PDE3A* are within systems with
721 existing drugs not currently linked to a known antihypertensive mechanism; they may offer
722 repurposing opportunities e.g. detection of *SLC5A1* as the strongest repurposing candidate
723 in a new BP locus targeted by the type-2 diabetes drug canagliflozin. This is important as
724 between 8-12% of patients with hypertension exhibit resistance or intolerance to current
725 therapies and repositioning of a therapy with a known safety profile may reduce
726 development costs.

727 This study strengthens our previously reported GRS analysis indicating that all BP elevating
728 alleles combined could increase systolic BP by 10 mm Hg or more across quintiles or deciles
729 of the population distribution, substantially increasing risk of cardiovascular events¹⁰. We
730 previously suggested that genotyping BP elevating variants in the young may lead to
731 targeted lifestyle intervention in early life that might attenuate the BP rise at older ages¹⁰.

732 We identified several BP-associated loci that are also associated with lifestyle traits,
733 suggesting shared genetic architecture between BP and lifestyle exposures⁵³. We adjusted
734 our BP GWAS analyses for BMI to control for possible confounding effects, though we
735 acknowledge the potential for collider bias⁵⁴. Nonetheless, our findings of possible genetic
736 overlap between loci associated with BP and lifestyle exposures could support renewed
737 focus on altering specific lifestyle measures known to affect BP⁵⁵.

738 Despite smaller sample sizes, we observed high concordance with direction of effects on BP
739 traits of BP variants in Africans (> 62%) and South Asians (> 72%). The GRS analyses show
740 that, in combination, BP variants identified in European analyses are associated with BP in
741 non-European ancestries, though effect sizes were 30-40% smaller.

742 Our use of a two- and one-stage GWAS design illustrates the value of this approach to
743 minimize the effects of stochastic variation and heterogeneity. The one-stage approach
744 included signals that had independent and concordant support ($P < 0.01$) from both UKB
745 and ICBP, reducing the impact of winners' curse on our findings. Indeed, all but two of the
746 210 SNPs discovered in the one-stage analysis reach $P < 5 \times 10^{-6}$ in either UKB or ICBP. To
747 further minimize the risk of reporting false positive loci within our one-stage design, we set
748 a stringent overall discovery meta-analysis P -value threshold of $P < 5 \times 10^{-9}$, an order of
749 magnitude smaller than a genome-wide significance P -value, in line with thresholds
750 recommended for whole genome sequencing²². We found high concordance in direction of
751 effects between discovery data in the one-stage approach and the replication resources,
752 with similar distributions of effect sizes for the two approaches. We note that 24 of the
753 one-stage SNPs which reached $P < 5 \times 10^{-9}$ in discovery failed to reach genome-wide
754 significance ($P < 5 \times 10^{-8}$) in the combined meta-analysis of discovery and replication
755 resources, and hence may still require further validation in future, larger studies.

756 The new discoveries reported here more than triple the number of loci for BP to a total of
757 901 and represent a substantial advance in understanding the genetic architecture of BP.
758 The identification of many novel genes across the genome, could partly support an
759 omnigenic model for complex traits where genome-wide association of multiple
760 interconnected pathways is observed. However, our strong tissue enrichment shows
761 particular relevance to the biology of BP and cardiovascular disease⁵⁶, suggesting trait-
762 specificity, which could argue against an omnigenic model. Our confirmation of the impact
763 of these variants on BP level and cardiovascular events, coupled with identification of
764 shared risk variants for BP and adverse lifestyle could contribute to an early life precision
765 medicine strategy for cardiovascular disease prevention.

1078 **Figure Legends**

1079 **Figure 1. Study design schematic for discovery and validation of loci.** ICBP; International
1080 Consortium for Blood Pressure; N, sample size; QC, quality control; PCA, principal-component
1081 analysis; GWAS, Genome-wide Association Study; 1000G 1000 Genomes; HRC, Haplotype Reference
1082 Panel; BP: blood pressure; SNPs, single nucleotide polymorphisms; BMI, body mass index; LMM;
1083 linear mixed model; UKB, UK Biobank, MAF, minor allele frequency; HLA, Human Leukocyte Antigen;
1084 MVP, Million Veterans Program; EGCTU; Estonian Genome Center, University of Tartu; SBP, systolic
1085 blood pressure; DBP, diastolic blood pressure; PP, pulse pressure.

1086 **Figure 2. Manhattan plot showing the minimum P -value for the association across all blood**
1087 **pressure traits in the discovery stage excluding known and previously reported variants.**
1088 Manhattan plot of the discovery genome-wide association meta-analysis in 757,601 individuals
1089 excluding variants in 274 known loci. The minimum P -value, computed using inverse variance fixed
1090 effects meta-analysis, across SBP, DBP and PP is presented. The y axis shows the $-\log_{10} P$ values and
1091 the x axis shows their chromosomal positions. Horizontal red and blue line represents the thresholds
1092 of $P = 5 \times 10^{-8}$ for genome-wide significance and $P = 1 \times 10^{-6}$ for selecting SNPs for replication,
1093 respectively. SNPs in blue are in LD ($r^2 > 0.8$) with the 325 novel variants independently replicated
1094 from the 2-stage design whereas SNPs in red are in LD ($r^2 > 0.8$) with 210 SNPs identified through the
1095 1-stage design with internal replication. Any loci in black or grey that exceed the significance
1096 thresholds were significant in the discovery meta-analysis, but did not meet the criteria of
1097 replication in the one- or two-stage designs.

1098 **Figure 3: Venn Diagrams of Novel Loci Results (a) “Comparison of 1-stage and 2-stage design**
1099 **analysis criteria”:** For all 535 novel loci, we compare the results according to the association criteria
1100 used for the one-stage and the two-stage design. Two-hundred and ten loci exclusively met the one-
1101 stage analysis criteria ($P < 5 \times 10^{-9}$ in the discovery meta-analysis [N=757,601], $P < 0.01$ in UKB
1102 [N=458,577], $P < 0.01$ in ICBP [N=299,024] and concordant direction of effect between UKB and
1103 ICBP). The P -values for the discovery and the ICBP meta-analyses were calculated using inverse
1104 variance fixed effects meta-analysis. The P -values in UKB were derived from linear mixed modeling
1105 using BOLT-LMM. Of the 325 novel replicated loci from the 2-stage analysis (genome-wide
1106 significance in the combined meta-analysis, $P < 0.01$ in the replication meta-analysis and concordant
1107 direction of effect), 204 loci would also have met the one-stage criteria, whereas 121 were only
1108 identified by the two-stage analysis. **(b) “Overlap of Associations across Blood Pressure Traits”.**
1109 For all 535 novel loci, we show the number of loci associated with each blood pressure trait. We
1110 present the two-stage loci first, followed by the one-stage loci. SBP: systolic blood pressure; DBP:
1111 diastolic blood pressure; PP: pulse pressure; UKB: UK Biobank; ICBP: International Consortium of
1112 Blood Pressure.

1113 **Figure 4. Association of blood pressure loci with lifestyle traits.** Plot shows unsupervised
1114 hierarchical clustering of BP loci based on associations with lifestyle-related factors. For the sentinel
1115 SNP at each BP locus (x-axis), we calculated the $-\log_{10}(P) * \text{sign}(\beta)$ (aligned to BP-raising allele) as
1116 retrieved from the Gene Atlas catalogue (<http://geneatlas.roslin.ed.ac.uk>). The P -values in Gene
1117 Atlas were calculated applying linear mixed models. BP loci and traits were clustered according to
1118 the Euclidean distance amongst $-\log_{10}(P) * \text{sign}(\beta)$. Red squares indicate direct associations with the
1119 trait of interest and blue squares inverse associations. Only SNPs with at least one association at P
1120 $< 10^{-6}$ with at least one of the traits examined are annotated in the heat-map. All 901 loci are
1121 considered, both known and novel: novel loci are printed in bold font. SNPs: Single Nucleotide
1122 Polymorphisms; BP: Blood Pressure.

1123 **Figure 5. Association of blood pressure loci with other traits.** Plot shows results from associations
1124 with other traits which were extracted from the GWAS catalog and PhenoScanner databases for the
1125 535 novel sentinel SNPs including proxies in Linkage Disequilibrium ($r^2 \geq 0.8$) with genome-wide
1126 significant associations. SBP: Systolic Blood Pressure; DBP: Diastolic Blood Pressure; PP: Pulse
1127 Pressure; HR: Heart Rate; ECG: Electrocardiographic traits; CAD: Coronary Artery Disease CHD;
1128 Coronary Heart Disease MI; Myocardial Infraction; T2D: Type II Diabetes.

1129 **Figure 6. Association of blood pressure loci with other traits.** Plots (a) and (b) show overlap
1130 between variants associated to (a) traits and (b) diseases in the manually-curated version of the
1131 DisGeNET database, and all variants in LD $r^2 > 0.8$ with the known (red bars) SNPs from the 274

1132 published loci, and all (green bars) BP variants from all 901 loci. Numbers on top of the bars denote
1133 the number of SNPs included in DisGeNET for the specific trait or disease. Traits/diseases with an
1134 overlap of at least 5 variants in LD with all markers are shown. The Y axis shows the percentage of
1135 variants associated with the diseases that is covered by the overlap. For the sake of clarity, the
1136 DisGeNET terms for blood pressure and hypertension are not displayed, whereas the following
1137 diseases have been combined: coronary artery disease (CAD), coronary heart disease (CHD) and
1138 myocardial infarction (MI); prostate and breast carcinoma; Crohn's and inflammatory bowel
1139 diseases.

1140 **Figure 7. Relationship of deciles of the genetic risk score (GRS) based on all 901 loci with blood**
1141 **pressure, risk of hypertension and cardiovascular disease in UK Biobank.** The plots show sex-
1142 adjusted (a) mean systolic blood pressure (SBP) and odds ratios of hypertension (HTN) (N=364,520)
1143 and (b) odds ratios of incident cardiovascular disease (CVD), myocardial infarction (MI) and stroke
1144 (N=392,092), comparing each of the upper nine GRS deciles with the lowest decile; dotted lines
1145 represent the upper 95% confidence intervals.

1146 **Figure 8: Known and novel BP associations in the TGF β signalling pathway.** Genes with known
1147 associations with BP are indicated in cyan. Genes with novel associations with BP reported in this
1148 study are indicated in red. TGF β pathway was derived from an ingenuity canonical pathway. BP:
1149 Blood Pressure.

1150

1151 **ONLINE METHODS**

1152 **UK Biobank (UKB) data**

1153 We performed a Genome Wide Association Study (GWAS) analysis in 458,577 UKB
1154 participants¹³ (**Supplementary Methods**). These consist of 408,951 individuals from UKB
1155 genotyped at 825,927 variants with a custom Affymetrix UK Biobank Axiom Array chip and
1156 49,626 individuals genotyped at 807,411 variants with a custom Affymetrix UK BiLEVE
1157 Axiom Array chip from the UK BiLEVE study⁵⁷, which is a subset of UKB. SNPs were imputed
1158 centrally by UKB using a reference panel that merged the UK10K and 1000 Genomes Phase
1159 3 panel as well as the Haplotype Reference Consortium (HRC) panel⁵⁸. For current analysis
1160 only SNPs imputed from the HRC panel were considered.

1161 *UKB phenotypic data*

1162 Following Quality Control (QC) (**Supplementary Methods**), we restricted our data to a
1163 subset of post-QC individuals of European ancestry combining information from self-
1164 reported and genetic data (**Supplementary Methods**) resulting in a maximum of N=458,577
1165 individuals (**Fig. 1, Supplementary Fig. 12**).

1166 Three BP traits were analysed: systolic (SBP), diastolic (DBP) and pulse pressure (PP)
1167 (difference between SBP and DBP). We calculated the mean SBP and DBP values from two
1168 automated (N=418,755) or two manual (N=25,888) BP measurements. For individuals with
1169 one manual and one automated BP measurement (N=13,521), we used the mean of these
1170 two values. For individuals with only one available BP measurement (N=413), we used this
1171 single value. After calculating BP values, we adjusted for medication use by adding 15 and
1172 10 mmHg to SBP and DBP, respectively, for individuals reported to be taking BP-lowering
1173 medication (N=94,289)⁵⁹. Descriptive summary statistics are shown in **Supplementary Table**
1174 **1a**.

1175 *UKB analysis models*

1176 For the UKB GWAS we performed linear mixed model (LMM) association testing under an
1177 additive genetic model of the three (untransformed) continuous, medication-adjusted BP
1178 traits (SBP, DBP, PP) for all measured and imputed genetic variants in dosage format using
1179 the BOLT-LMM (v2.3) software¹⁷. We also calculated the estimated SNP-wide heritability
1180 (h^2) in our data. Within the association analysis, we adjust for the following covariates: sex,
1181 age, age², BMI and a binary indicator variable for UKB vs UK BiLEVE to account for the
1182 different genotyping chips. The analysis of all HRC-imputed SNPs was restricted to variants
1183 with MAF \geq 1% and INFO > 0.1.

1184 *Genomic inflation and confounding*

1185 We applied the univariate LD score regression method (LDSR)¹⁸ to test for genomic inflation
1186 (expected for polygenic traits like BP, with large sample sizes, and especially also from
1187 analyses of such dense genetic data with many SNPs in high LD)⁶⁰. LDSR intercepts (and

1188 standard errors) were 1.217 (0.018), 1.219 (0.020) and 1.185 (0.017) for SBP, DBP and PP
1189 respectively, and were used to adjust the UKB GWAS results for genomic inflation, prior to
1190 the meta-analysis.

1191 **International Consortium for Blood Pressure (ICBP) GWAS**

1192 ICBP GWAS is an international consortium to investigate BP genetics⁶. We combined
1193 previously reported post-QC GWAS data from 54 studies (N=150,134)^{11,12,61}, with newly
1194 available GWAS data from a further 23 independent studies (N=148,890) using a fixed
1195 effects inverse variance weighted meta-analysis. The 23 studies providing new data were:
1196 ASCOT-SC, ASCOT-UK, BRIGHT, Dijon 3C, EPIC-CVD, GAPP, HCS, GS:SFHS, Lifelines, JUPITER,
1197 PREVEND, TWINSUK, GWAS-Fenland, InterAct-GWAS, OMICS-EPIC, OMICS-Fenland, UKHLS,
1198 GoDARTS-Illumina and GoDarts-Affymetrix, NEO, MDC, SardinIA, METSIM.

1199 All study participants were Europeans and were imputed to either the 1000 Genomes
1200 Project Phase 1 integrated release v.3 [March 2012] all ancestry reference panel⁶² or the
1201 HRC panel¹⁶. The final enlarged ICBP GWAS dataset included 77 cohorts (N=299,024).

1202 Full study names, cohort information and general study methods are included in
1203 **Supplementary Table 1b** and in **Supplementary Tables 20a-c**. GC was applied at study-level.
1204 The LDSR intercepts (standard error) for the ICBP GWAS meta-analysis were 1.089 (0.012),
1205 1.086 (0.012) and 1.066 (0.011) for SBP, DBP and PP, respectively.

1206 **Meta-analyses of discovery datasets**

1207 We performed a fixed-effects inverse variance weighted meta-analysis using METAL^{20,63} to
1208 obtain summary results from the UKB and ICBP GWAS, for up to N=757,601 participants and
1209 ~7.1 M SNPs with MAF \geq 1% for variants present in both the UKB data and ICBP meta-
1210 analysis for all three traits. The LDSR intercepts (standard error), in the discovery meta-
1211 analysis of UKB and ICBP were 1.156 (0.020), 1.160 (0.021) and 1.113 (0.018) for SBP, DBP
1212 and PP respectively. The LDSR intercept (standard error), after the exclusion of all published
1213 BP variants (see below) in the discovery meta-analysis of UKB and ICBP was 1.090 (0.018),
1214 1.097 (0.017) and 1.064 (0.015) for SBP, DBP and PP respectively, hence showing little
1215 inflation in the discovery GWAS after the exclusion of published loci (**Supplementary Fig.**
1216 **13**). No further correction was applied to the discovery meta-analysis of UKB and ICBP
1217 GWAS.

1218 **Previously reported variants**

1219 We compiled from the peer-reviewed literature all 357 SNPs previously reported to be
1220 associated with BP at the time that our analysis was completed, that have been identified
1221 and validated as the sentinel SNP in primary analyses from previous BP genetic association
1222 studies. These 357 published SNPs correspond to 274 distinct loci, according to locus
1223 definition of: (i) SNPs within \pm 500kb distance of each other; (ii) SNPs in Linkage
1224 Disequilibrium (LD), using a threshold of $r^2 \geq$ 0.1, calculated with PLINK (v2.0). We then

1225 augment this list to all SNPs present within our data, which are contained within these 274
1226 published BP loci, i.e. all SNPs which are located $\pm 500\text{kb}$ from each of the 357 published
1227 SNPs and/or in LD with any of the 357 previously validated SNPs ($r^2 \geq 0.1$).

1228 **Identification of novel signals: Two-stage and one-stage study designs**

1229 To identify novel signals of association with BP, two complementary study designs (which
1230 we term here “two-stage design” and “one-stage design”) were implemented in order to
1231 maximize the available data and minimize reporting of false positive associations.

1232 **Two-stage design: Overview:**

1233 All of the following criteria had to be satisfied for a signal to be reported as a novel signal of
1234 association with BP using our two-stage design:

- 1235 (i) the sentinel SNP shows significance ($P < 1 \times 10^{-6}$) in the discovery meta-analysis
1236 of UKB and ICBP, with concordant direction of effect between UKB and ICBP;
- 1237 (ii) the sentinel SNP is genome-wide significant ($P < 5 \times 10^{-8}$) in the combined meta-
1238 analysis of discovery and replication (MVP and EGCUT) (replication, described
1239 below);
- 1240 (iii) the sentinel SNP shows support ($P < 0.01$) in the replication meta-analysis of
1241 MVP and EGCUT alone (**Supplementary Methods**);
- 1242 (iv) the sentinel SNP has concordant direction of effect between the discovery and
1243 the replication meta-analyses;
- 1244 (v) the sentinel SNP must not be located within any of the 274 previously reported
1245 loci described above.

1246 The primary replicated trait was then defined as the BP trait with the most significant
1247 association from the combined meta-analysis of discovery and replication (in the case
1248 where a SNP was replicated for more than one BP trait.)

1249 **Two-stage design: Selection of variants from the discovery meta-analysis**

1250 We considered for follow-up SNPs in loci non-overlapping with previously reported loci
1251 according to both an LD threshold at r^2 of 0.1 and a 1Mb interval region, as calculated by
1252 PLINK⁶⁴. We obtained a list of such SNPs with $P < 1 \times 10^{-6}$ for any of the three BP traits,
1253 which also had concordant direction of effect between UKB vs ICBP (**Supplementary Table**
1254 **21**). By ranking the SNPs by significance in order of minimum P-value across all BP traits, we
1255 performed an iterative algorithm to determine the number of novel signals (**Supplementary**
1256 **Methods**), and identify the sentinel SNP (most significant) per locus.

1257 **Two-stage design: Replication analysis**

1258 We considered SNPs with $\text{MAF} \geq 1\%$ for an independent replication in MVP (max
1259 $N=220,520$)¹⁴ and in EGCUT Biobank ($N=28,742$)¹⁵ (**Supplementary Methods**). This provides
1260 a total of $N=249,262$ independent samples of European descent available for replication.

1261 Additional information on the analyses of the two replication datasets is provided in
1262 **Supplementary Methods** and in **Supplementary Table 1c**.

1263 The two datasets were then combined using fixed effects inverse variance weighted meta-
1264 analysis and summary results for all traits were obtained for the replication meta-analysis
1265 dataset.

1266 **Two-stage design: Combined meta-analysis of discovery and replication meta-analyses**

1267 The meta-analyses were performed within METAL software⁶³ using fixed effects inverse
1268 variance weighted meta-analysis (**Supplementary Methods**). The variants from the
1269 discovery GWAS that required proxies for replication are shown in **Supplementary Table 22**.
1270 The combined meta-analysis of both the discovery data (N=757,601) and replication meta-
1271 analysis (max N=249,262) provided a maximum sample size of N=1,006,863.

1272 **One-stage design: Overview**

1273 Variants that were looked-up but did not replicate according to the two-stage criteria were
1274 considered in a one-stage design. All of the following criteria had to be satisfied for a signal
1275 to be reported as a novel signal of association with BP using our one-stage criteria:

- 1276 i) the sentinel SNP has $P < 5 \times 10^{-9}$ in the discovery (UKB+ICBP) meta-analysis;
- 1277 ii) the sentinel SNP shows support ($P < 0.01$) in the UKB GWAS alone;
- 1278 iii) the sentinel SNP shows support ($P < 0.01$) in the ICBP GWAS alone;
- 1279 iv) the sentinel SNP has concordant direction of effect between UKB and ICBP
1280 datasets;
- 1281 v) The sentinel SNP must not be located within any of the 274 previously reported
1282 loci described above (**Supplementary Table 4**) or the recently reported non-
1283 replicated loci from Hoffman et al⁹ (**Supplementary Table 23**).

1284 We selected the one-stage P -value threshold to be an order of magnitude more stringent
1285 than a genome-wide significance P -value, so as to ensure robust results and to minimize
1286 false positive findings. The threshold of $P < 5 \times 10^{-9}$ has been proposed as a more
1287 conservative statistical significance threshold, e.g. for whole-genome sequencing-based
1288 studies²¹.

1289 Selection of variants from the meta-analysis of UKB and ICBP was performed as described
1290 above for the two-stage design.

1291 **Conditional Analysis**

1292 We performed conditional analyses using the GWAS discovery meta-analysis data, in order
1293 to identify any independent secondary signals in addition to the sentinel SNPs at the 901
1294 loci. We used two different methodological approaches, each using the Genome-wide
1295 Complex Traits Analysis (GCTA) software²²: (i) full “genome-wide conditional analysis” with
1296 joint multivariate analysis and stepwise model selection across all three BP traits; and (ii)
1297 “locus-specific conditional analysis” for the primary BP trait conditioning on the sentinel

1298 SNPs within each locus (**Supplementary Methods**). For robustness, secondary signals are
1299 only reported if obtained from both approaches. All secondary signals were selected at
1300 genome-wide significance level, with $MAF \geq 1\%$ and confirmed to be pairwise-LD-
1301 independent ($r^2 < 0.1$), as well as not being in LD with any of the published or sentinel SNPs
1302 at any of the 901 BP-associated loci ($r^2 < 0.1$). In all cases the UKB data was used as the
1303 reference genetic data for LD calculation, restricted to individuals of European ancestry
1304 only.

1305 **Functional analyses: Variants**

1306 We used an integrative bioinformatics approach to collate functional annotation at both the
1307 variant level (for each sentinel SNP within all BP loci) and the gene level (using SNPs in LD r^2
1308 ≥ 0.8 with the sentinel SNPs). At the variant level, we use Variant Effect Predictor (VEP) to
1309 obtain comprehensive characterization of variants, including consequence (e.g. downstream
1310 or non-coding transcript exon), information on nearest genomic features and, where
1311 applicable, amino acid substitution functional impact, based on SIFT and PolyPhen. The
1312 biomaRt R package is used to further annotate the nearest genes.

1313 We evaluated all SNPs in LD ($r^2 \geq 0.8$) with our novel sentinel SNPs for evidence of mediation
1314 of expression quantitative trait loci (eQTL) in all 44 tissues using the Genotype-Tissue
1315 Expression (GTEx) database, to highlight specific tissue types which show eQTLs for a larger
1316 than expected proportion of novel loci. We further seek to identify novel loci with the
1317 strongest evidence of eQTL associations in arterial tissue, in particular. A locus is annotated
1318 with a given eGene only if the most significant eQTL SNP for the given eGene is in high LD (r^2
1319 ≥ 0.8) with the sentinel SNP, suggesting that the eQTL signal co-localises with the sentinel
1320 SNP.

1321 We annotated nearest genes, eGenes (genes whose expression is affected by eQTLs) and Hi-
1322 C interactors with HUVEC, HVMSC and HAEC expression from the Fantom5 project. Genes
1323 that had higher than median expression levels in the given cell types were indicated as
1324 expressed.

1325 To identify SNPs in the novel loci that have a non-coding functional effect (influence binding
1326 of transcription factors or RNA polymerase, or influence DNase hypersensitivity sites or
1327 histone modifications), we used DeepSEA, a deep learning algorithm, that learnt the binding
1328 and modification patterns of ~ 900 cell/factor combinations⁶⁵. A change of >0.1 in the
1329 binding score predicted by DeepSEA for the reference and alternative alleles respectively
1330 was used as cut-off to find alleles with non-coding functional effect (**Supplementary**
1331 **Methods**)

1332 We identified potential target genes of regulatory SNPs using long-range chromatin
1333 interaction (Hi-C) data from HUVECs²³, aorta, adrenal glands, neural progenitor and
1334 mesenchymal stem cell, which are tissues and cell types that are considered relevant for
1335 regulating BP²⁴. We find the most significant promoter interactions for all potential

1336 regulatory SNPs (RegulomeDB score ≤ 5) in LD ($r^2 \geq 0.8$) with our novel sentinel SNPs and
1337 published SNPs, and choose the interactors with the SNPs of highest regulatory potential to
1338 annotate the loci.

1339 We then performed overall enrichment testing across all loci. Firstly, we used DEPICT⁶⁶
1340 (Data-driven Expression Prioritized Integration for Complex Traits) to identify tissues and
1341 cells which are highly expressed at genes within the BP loci (**Supplementary Methods**).
1342 Secondly, we used DEPICT to test for enrichment in gene sets associated with biological
1343 annotations (manually curated and molecular pathways, phenotype data from mouse KO
1344 studies) (**Supplementary Methods**). We report significant enrichments with a false
1345 discovery rate < 0.01 . The variants tested were i) the 357 published BP associated SNPs at
1346 the time of analysis and ii) a set including all (published and novel) variants (with novel SNPs
1347 filtered by highest significance, $P < 1 \times 10^{-12}$).

1348 Furthermore, to investigate cell type specific enrichment within DNase I sites, we used
1349 FORGE, which tests for enrichment of SNPs within DNase I sites in 123 cell types from the
1350 Epigenomics Roadmap Project and ENCODE²⁵ (**Supplementary Methods**). Two analyses
1351 were compared (i) using published SNPs only; (ii) using sentinel SNPs at all 901 loci, in order
1352 to evaluate the overall tissue specific enrichment of BP associated variants.

1353 **Functional analyses: Genes**

1354 At the gene level, we used Ingenuity Pathway Analysis (IPA) software (IPA®, QIAGEN
1355 Redwood City) to review genes with prior links to BP, based on annotation with the
1356 “Disorder of Blood Pressure”, “Endothelial Development” and “Vascular Disease” Medline
1357 Subject Heading (MESH) terms. We used the Mouse Genome Informatics (MGI) tool to
1358 identify BP and cardiovascular relevant mouse knockout phenotypes for all genes linked to
1359 BP in our study. We also used IPA to identify genes that interact with known targets of anti-
1360 hypertensive drugs. Genes were also evaluated for evidence of small molecule druggability
1361 or known drugs based on queries of the Drug Gene Interaction database.

1362 **Lookups in non-European ancestries**

1363 As a secondary analysis, we look up all known and novel BP-associated SNPs in Africans
1364 (7,782) and South Asians (10,322) from UKB using BOLT-LMM analysis for each BP trait
1365 within each ancestry (**Supplementary Methods**).

1366 **Effects on other traits and diseases**

1367 We queried SNPs against GWAS catalog²⁶ and PhenoScanner²⁷, including genetics and
1368 metabolomics databases, to investigate cross-trait effects, extracting all association results
1369 with genome-wide significance at $P < 5 \times 10^{-8}$ for all SNPs in high LD ($r^2 \geq 0.8$) with the 535
1370 sentinel novel SNPs, to highlight the loci with strongest evidence of association with other
1371 traits. We further evaluated these effects using DisGeNET^{28,29}. At the gene level,
1372 overrepresentation enrichment analysis (ORA) with WebGestalt⁶⁷ on the nearest genes to
1373 all BP loci was carried out. Moreover, we tested sentinel SNPs at all published and novel

1374 (N=901) loci for association with lifestyle related data including food, water and alcohol
1375 intake, anthropomorphic traits and urinary sodium, potassium and creatinine excretion
1376 using the recently developed Stanford Global Biobank Engine and the Gene ATLAS⁶⁸. Both
1377 are search engines for GWAS findings for multiple phenotypes in UK Biobank. We used a
1378 Bonferroni corrected significance threshold of $P < 1 \times 10^{-6}$ to deem significance.

1379 **Genetic risk scores and percentage of variance explained**

1380 We calculated a weighted genetic risk score (GRS) (**Supplementary Table 24**) to provide an
1381 estimate of the combined effect of the BP raising variants on BP and risk of hypertension
1382 and applied this to the UKB data (**Supplementary Methods**). Our analysis included 423,713
1383 unrelated individuals of European ancestry of whom 392,092 individuals were free of
1384 cardiovascular events at baseline.

1385 We assessed the association of the continuous GRS variable on BP and with the risk of
1386 hypertension, with and without adjustment for sex. We then compared BP levels and risk of
1387 hypertension, respectively, for individuals in the top vs bottom quintiles of the GRS
1388 distribution. Similar analyses were performed for the top vs bottom deciles of the GRS
1389 distribution. All analyses were restricted to the 392,092 unrelated individuals of European
1390 ancestry from UKB. As a sensitivity analysis to assess for evidence of bias in the UKB results,
1391 we also carried out similar analyses in Airwave, an independent cohort of N=14,004
1392 unrelated participants of European descent³⁰ (**Supplementary Methods**).

1393 We calculated the association of the GRS with cardiovascular disease in unrelated
1394 participants in UKB data, based on self-reported medical history, and linkage to
1395 hospitalization and mortality data (**Supplementary Table 25**). We use logistic regression
1396 with binary outcome variables for composite incident cardiovascular disease
1397 (**Supplementary Methods**), incident myocardial infarction and incident stroke (using the
1398 algorithmic UKB definitions) and GRS as explanatory variable (with and without sex
1399 adjustment).

1400 We also assessed the association of this GRS with BP in unrelated individuals Africans
1401 (N=6,970) and South Asians (N=8,827) from the UKB to see whether BP-associated SNPs
1402 identified from GWAS predominantly in Europeans are also associated with BP in
1403 populations of non-European ancestry.

1404 We calculated the percentage of variance in BP explained by genetic variants using the
1405 independent Airwave cohort (N=14,004) (**Supplementary Methods**). We considered three
1406 different levels of the GRS: (i) all pairwise-independent, LD-filtered ($r^2 < 0.1$) published SNPs
1407 within the known loci; (ii) all known SNPs and sentinel SNPs at novel loci; (iii) all
1408 independent signals at all 901 known and novel loci including the 163 secondary SNPs.

1409 **Data availability statement**

1410 The UKB GWAS data can be accessed from the UK Biobank data repository
1411 (<http://biota.osc.ox.ac.uk/>). The genetic and phenotypic UKB data are available upon

1412 application to the UK Biobank (<https://www.ukbiobank.ac.uk>). ICBP summary data can be
1413 assessed through request to ICBP steering committee. Contact Mark Caulfield
1414 (m.j.caulfield@qmul.ac.uk) or Paul Elliott (p.elliott@imperial.ac.uk) to apply for access to
1415 the data. The UKB+ICBP summary data can be assessed through request to Paul Elliott
1416 (p.elliott@imperial.ac.uk) or Mark Caulfield (m.j.caulfield@qmul.ac.uk). All replication data
1417 generated during this study are included in the published article. For example, association
1418 results of look-up variants from our replication analyses and the subsequent combined
1419 meta-analyses are contained within the Supplementary Tables provided.

1420 **Reporting Summary**

1421 Further information on experimental design is available in the Life Sciences Reporting
1422 Summary linked to this article.

1423 **Ethics Statement**

1424 The UKB study has approval from the North West Multi-Centre Research Ethics Committee.
1425 Any participants from UKB who withdrew consent have been removed from our analysis.
1426 Each cohort within the ICBP meta-analysis as well as our independent replication cohorts of
1427 MVP and EGCUT had ethical approval locally. More information on the participating cohorts
1428 is available in **Supplementary Methods**.
